The Course

Instructor: Prof. Purvi Gupta

Office: L-25

Office hours: Wed 17:00–18:00

Lecture hours: MW 12:00–12:50, Thu 9:00–9:50

Tutorial hours: Fri 12:00–12:50

We assume the following.

- Basics of set theory
- Existence of $\mathbb{N} = \{0, 1, 2, \dots\}$ with the usual operations $+$ and \cdot

For a recap, refer lectures 1 to 3 of UMA101.

Lecture 1.

Monday

January 01

Chapter I

Number Systems

$$\mathbb{N} \subseteq \mathbb{Z} \subseteq \mathbb{Q} \subseteq \mathbb{R} \subseteq \mathbb{C}$$

I.1 The Naturals

(Recall from UM101) \mathbb{N} is the unique minimal inductive set granted by the ZFC axioms. Addition and multiplication are defined by the recursion principle and we showed that they

- are associative and commutative,
- admit identity elements 0 and 1 respectively,
- satisfy the distributive law,
- satisfy cancellation laws,
- but do **not** admit inverses.

I.2 Relations

(Recall) A relation on a set A is a subset $R \subseteq A \times A$. We write $a R b$ to denote $(a, b) \in R$.

Definition I.2.1 (Partial order). A relation R on A is called a *partial order* if it is

- reflexive – $a R a$ for all $a \in A$;
- antisymmetric – if $a R b$ and $b R a$ then $a = b$ for all $a, b \in A$;
- transitive – if $a R b$ and $b R c$ then $a R c$ for all $a, b, c \in A$.

Additionally, if for all $x, y \in A$, $x R y$ or $y R x$, then R is called a *total order*.

A set A equipped with a partial order \leq is called a *partially ordered set* (or *poset*).

A set A equipped with a total order \leq is called a *totally ordered set* or simply an *ordered set*.

Examples.

- (\mathbb{N}, \leq) where we say that $a \leq b$ if $\exists c \in \mathbb{N}$ such that $a + c = b$.
- $(\mathbb{N}, |)$ where we say that $a | b$ if $\exists c \in \mathbb{N}$ such that $a \cdot c = b$.

In UMA101, we defined order slightly differently, where we said that either $a < b$ or $b < a$ but never both. This is a “strict order”. We will denote a weak partial order by \leq and a strict partial order by $<$. (the notation is suggestive of how to every order there is a corresponding strict order and vice versa).

Definition I.2.2 (Equivalence). An *equivalence relation* on a set A is a relation R satisfying

- reflexivity;
- symmetry – if $a R b$ then $b R a$ for all $a, b \in A$;
- transitivity.

Notation. We write $[x]_R$ to denote the set $\{y \in A \mid x R y\}$.

Proposition I.2.3. The collection $\mathcal{A} = \{[x]_R \mid x \in A\}$ partitions A under any equivalence relation R on A .

Proof. For every $x \in A$, $x \in [x]_R$ and so $\bigcup \mathcal{A} = A$.

Let $[x]_R \cap [y]_R \neq \emptyset$, where $x, y \in A$. Then there exists $z \in A$ such that $x R z$ and $y R z$, from which it follows that $x R y$ and $[x]_R = [y]_R$. \square

I.3 The Integers

We cannot solve $3 + x = 2$ in \mathbb{N} . We introduce \mathbb{Z} to solve this problem.

Consider the relation R on $\mathbb{N} \times \mathbb{N}$ given by

$$(a, b) R (c, d) \iff a + d = b + c.$$

(check that this is an equivalence relation trivial).

Definition I.3.1. We define \mathbb{Z} to be the set of equivalence classes of R , denoted $(\mathbb{N} \times \mathbb{N})/R$.

Further, define

Definition I.3.2.

- $[(a, b)] +_{\mathbb{Z}} [(c, d)] := [(a + c, b + d)];$
- $[(a, b)] \cdot_{\mathbb{Z}} [(c, d)] := [(ac + bd, ad + bc)].$
- $z_1 \leq_{\mathbb{Z}} z_2$ iff there exists $n \in \mathbb{N}$ such that $z_1 +_{\mathbb{Z}} [(n, 0)] = z_2$
(alternatively, $[(a, b)] \leq_{\mathbb{Z}} [(c, d)]$ iff $a + d \leq b + c$).

We need to check that these are well-defined. What does this mean?
Consider

$$\begin{aligned} [(1, 2)] +_{\mathbb{Z}} [(3, 4)] &= [(4, 6)] \\ [(3, 4)] +_{\mathbb{Z}} [(3, 4)] &= [(6, 8)] \end{aligned}$$

Our definition must ensure that $[(4, 6)] = [(6, 8)]$.

In general, the definitions are well-defined if they are independent of the choice of representatives.

Throughout this section, we will omit the parentheses in $[(a, b)]$ and write it as $[a, b]$.

Lecture 2.
Tuesday
January 02

Proposition I.3.3. The operations $+_{\mathbb{Z}}$, $\cdot_{\mathbb{Z}}$ and the relation $\leq_{\mathbb{Z}}$ are well-defined.

Proof. Suppose $x = [a, b] = [a', b']$ and $y = [c, d] = [c', d']$. Then

$$\begin{aligned} a + b' &= a' + b \\ c + d' &= c' + d \\ (a + c) + (b' + d') &= (a' + c') + (b + d) \\ (a + c, b + d) &R (a' + c', b' + d') \\ [a + c, b + d] &= [a' + c', b' + d'] \end{aligned}$$

Since $\leq_{\mathbb{Z}}$ is defined in terms of $+\mathbb{Z}$, it is also well-defined. For multiplication,

$$\begin{aligned} (a + b')c + (a' + b)d &= (a' + b)c + (a + b')d \\ (ac + bd) + (a'd + b'c) &= (a'c + b'd) + (ad + bc) \\ [ac + bd, ad + bc] &= [a'c + b'd, a'd + b'c] \end{aligned}$$

and symmetrically

$$[a'c + b'd, a'd + b'c] = [a'c' + b'd', a'c' + b'd']$$

so by transitivity

$$[ac + bd, ad + bc] = [a'c' + b'd', a'c' + b'd'] \quad \square$$

Proposition I.3.4. *The relation $\leq_{\mathbb{Z}}$ is a total order on \mathbb{Z} .*

Proof. Let $x = [a, b], y = [c, d] \in \mathbb{Z}$. Since $x +_{\mathbb{Z}} [0, 0] = [a + 0, b + 0] = x$, $x \leq_{\mathbb{Z}} x$.

Suppose $x \leq_{\mathbb{Z}} y$ and $y \leq_{\mathbb{Z}} x$. Then there exist $m, n \in \mathbb{N}$ such that $x + [m, 0] = y$ and $y +_{\mathbb{Z}} [n, 0] = x$. Thus $x +_{\mathbb{Z}} [m, 0] +_{\mathbb{Z}} [n, 0] = [a + m + n, b] = [a, b]$. This gives $a + m + n + b = a + b$ and so $m + n = 0$. This can only be when $m = n = 0$ and so $x = y$.

Now suppose $x \leq_{\mathbb{Z}} y$ and $y \leq_{\mathbb{Z}} z$. Then there exist $m, n \in \mathbb{N}$ such that $x + [m, 0] = y$ and $y +_{\mathbb{Z}} [n, 0] = z$. This immediately gives $x + [m + n, 0] = z$ and so $x \leq_{\mathbb{Z}} z$.

For trichotomy, note that either $a + d \leq b + c$ or $b + c \leq a + d$ by trichotomy of (\mathbb{N}, \leq) . In the first case, $a + d + n = b + c$ for some $n \in \mathbb{N}$, so $[a, b] +_{\mathbb{Z}} [n, 0] = [c, d]$. Thus $x \leq_{\mathbb{Z}} y$. Similarly, in the second case, $y \leq x$. \square

Definition I.3.5 (Ring). A *ring* is a set S with two binary operations $+$ and \cdot such that for all $a, b, c \in S$,

(R1) addition is associative,

- (R2) addition is commutative,
- (R3) there exists an additive identity 0,
- (R4) there exists an additive inverse $-a$,
- (R5) multiplication is associative,
- (R6) there exists a multiplicative identity 1,
- (R7) multiplication is distributive over addition (on both sides).

For a *commutative ring*, we require additionally that

- (CR1) multiplication is commutative.

Note that inverses are unique, since if $a + b = 0$ and $a + b' = 0$, then $b = (b' + a) + b = b' + (a + b) = b'$.

Definition I.3.6 (Ordered Ring). An *ordered ring* is a ring S with a total order \leq such that for all $a, b, c \in S$,

- (OR1) $a \leq b$ implies $a + c \leq b + c$,
- (OR2) $0 \leq a$ and $0 \leq b$ implies $0 \leq ab$.

Theorem I.3.7.

- $(\mathbb{Z}, +_{\mathbb{Z}}, \cdot_{\mathbb{Z}}, \leq_{\mathbb{Z}})$ is an ordered (commutative) ring.
- The map $f = n \mapsto [n, 0]$ from \mathbb{N} to \mathbb{Z} is an injective map that respects $+$, \cdot and \leq . That is, for all $n, m \in \mathbb{N}$,
 - (i) $f(n + m) = f(n) +_{\mathbb{Z}} f(m)$,
 - (ii) $f(nm) = f(n) \cdot_{\mathbb{Z}} f(m)$,
 - (iii) $n \leq m \iff f(n) \leq_{\mathbb{Z}} f(m)$.

In other words, f is an isomorphism onto a subset of \mathbb{Z} .

Proof. For the first part of the theorem, we check all commutative ring axioms. We omit the subscripts on $+$ and \cdot for brevity.

(R1) Addition is associative:

$$\begin{aligned}
 ([a, b] + [c, d]) + [e, f] &= [a + c, b + d] + [e, f] \\
 &= [a + c + e, b + d + f] \\
 &= [a, b] + [c + e, d + f] \\
 &= [a, b] + ([c, d] + [e, f])
 \end{aligned}$$

(R2) Addition is commutative: immediate from commutativity of $+$ on \mathbb{N} .

(R3) Additive identity: $[a, b] + [0, 0] = [a + 0, b + 0] = [a, b]$.

(R4) Additive inverse: $[a, b] + [b, a] = [a + b, b + a] = [0, 0]$ since $a + b + 0 = b + a + 0$.

(R5) Multiplication is associative:

$$\begin{aligned}
 ([a, b] \cdot [c, d]) \cdot [e, f] &= [ac + bd, ad + bc] \cdot [e, f] \\
 &= [ace + bde + adf + bcf, ade + bce + acf + bdf] \\
 &= [a(ce + df) + b(cf + de), a(cf + de) + b(ce + df)] \\
 &= [a, b] \cdot [ce + df, cf + de] \\
 &= [a, b] \cdot ([c, d] \cdot [e, f])
 \end{aligned}$$

(R6) Multiplicative identity: $[a, b] \cdot [1, 0] = [a, b]$.

(R7) Multiplication distributes over addition:

$$\begin{aligned}
 [a, b] \cdot ([c, d] + [e, f]) &= [a, b] \cdot [c + e, d + f] \\
 &= [ac + ae + bd + bf, ad + af + bc + be] \\
 &= [ac + bd, ad + bc] + [ae + bf, af + be] \\
 &= [a, b] \cdot [c, d] + [a, b] \cdot [e, f]
 \end{aligned}$$

Distributivity on the other side follows from commutativity proved below.

For commutativity of multiplication,

$$\begin{aligned}
 [a, b] \cdot [c, d] &= [ac + bd, ad + bc] \\
 &= [ca + db, cb + da] \\
 &= [c, d] \cdot [a, b]
 \end{aligned}$$

(OR1) follows immediately from the definition. For (OR2), suppose $0 \leq x, y \in \mathbb{Z}$. Then $x = [n, 0]$ and $y = [m, 0]$ for some $n, m \in \mathbb{N}$. Thus $xy = [nm, 0]$ and so $0 \leq xy$.

The second part is again yawningly brute force.

- (i) $f(n + m) = [n + m, 0] = [n, 0] + [m, 0] = f(n) +_{\mathbb{Z}} f(m)$.
- (ii) $f(nm) = [nm, 0] = [n, 0] \cdot [m, 0] = f(n) \cdot_{\mathbb{Z}} f(m)$.
- (iii) $n \leq m \iff \exists k \in \mathbb{N}(n + k = m) \iff \exists k \in \mathbb{N}([n, 0] + [k, 0] = [m, 0]) \iff f(n) \leq_{\mathbb{Z}} f(m)$. \square

Thus, we may view $(\mathbb{N}, +, \cdot, \leq)$ as a subset of $(\mathbb{Z}, +_{\mathbb{Z}}, \cdot_{\mathbb{Z}}, \leq_{\mathbb{Z}})$, denote $[n, 0]$ as n and drop \mathbb{Z} in the subscript. We further define $-[a, b] := [b, a]$ and $z_1 - z_2 := z_1 + (-z_2)$.

Moreover, we have the following properties.

Proposition I.3.8.

- *There are no zero divisors in \mathbb{Z} . That is, for all $x, y \in \mathbb{Z}$, $xy = 0$ implies $x = 0$ or $y = 0$.*
- *The cancellation laws hold: for all $x, y, z \in \mathbb{Z}$, $x + y = x + z$ implies $y = z$, and $xy = xz$ implies $x = 0$ or $y = z$.*
- *(trichotomy) For all $z \in \mathbb{Z}$, $z = n$ or $z = -n$ for some $n \in \mathbb{N}$.*

Proof.

- From trichotomy proven below, we have $x = n$ or $x = -n$ and $y = m$ or $y = -m$ for some $n, m \in \mathbb{N}$. In any case $xy = nm$ or $xy = -nm$. Since there are no zero divisors in \mathbb{N} , $xy = 0$ implies $n = 0$ or $m = 0$, which in turn implies $x = 0$ or $y = 0$.
- The first cancellation law follows from the fact that additive inverses exist. For the second, note that $xy = xz \iff x(y - z) = 0$ and invoke the fact that there are no zero divisors.

Here we have also used that $-xz = x(-z)$, since $-\tilde{z} = -1 \cdot \tilde{z}$ for all $\tilde{z} \in \mathbb{Z}$, and multiplication is associative and commutative.

- Let $z = [a, b]$. From trichotomy of \leq on \mathbb{N} we know that either $a + n = b$ or $a = b + n$ for some $n \in \mathbb{N}$. That is, either $z = [0, n] = -n$, or $z = [n, 0] = n$. \square

I.4 The Rationals

We cannot solve $3x = 2$ in \mathbb{Z} .

Proof. For $x \leq 0$, $3x \leq 0 < 2$. For $x \geq 1$, $3x \geq 3 > 2$. \square

We define \mathbb{Z}^* to be $\mathbb{Z} \setminus \{0\}$ and define the relation R on $\mathbb{Z} \times \mathbb{Z}^*$ by $(a, b)R(c, d)$ if $ad = bc$. Then R is an equivalence relation on $\mathbb{Z} \times \mathbb{Z}^*$.

Definition I.4.1. We define \mathbb{Q} to be the set of equivalence classes of R , denoted $(\mathbb{Z} \times \mathbb{Z}^*)/R$.

We define operations $+_{\mathbb{Q}}$ and $\cdot_{\mathbb{Q}}$ on \mathbb{Q} by

$$\begin{aligned} [(a, b)] +_{\mathbb{Q}} [(c, d)] &:= [(ad + bc, bd)] \\ [(a, b)] \cdot_{\mathbb{Q}} [(c, d)] &:= [(ac, bd)] \end{aligned}$$

Since there are no zero divisors in \mathbb{Z} , $bd \neq 0$.

We define an order $\leq_{\mathbb{Q}}$ on \mathbb{Q} by

$$[(a, b)] \leq_{\mathbb{Q}} [(c, d)] \iff (ad - bc)bd \leq 0.$$

We will again omit the parentheses in this section.

Proposition I.4.2. The operations $+_{\mathbb{Q}}$, $\cdot_{\mathbb{Q}}$ and the relation $\leq_{\mathbb{Q}}$ are well-defined.

Proof. Suppose $[a, b] = [a', b']$ and $[c, d] = [c', d']$. Then

$$\begin{aligned} ab' &= a'b \\ cd' &= c'd \\ (ad + bc)(b'd') &= (a'd' + b'c')(bd) \\ [ad + bc, bd] &= [a'd' + b'c', b'd'] \end{aligned}$$

For multiplication,

$$\begin{aligned} (ac)(b'd') &= (a'c')(bd) \\ [ac, bd] &= [a'c', b'd'] \end{aligned}$$

For order,

$$\begin{aligned}
 & (ad - bc)bd \leq 0 \\
 \iff & (b'd')(ad - bc)bd(b'd') \leq 0 \\
 \iff & (ab'dd' - bb'cd')bdb'd' \leq 0 \\
 \iff & (a'bdd' - bb'c'd)bdb'd' \leq 0 \\
 \iff & (bd)^2(a'd' - b'c')b'd' \leq 0 \\
 \iff & (a'd' - b'c')b'd' \leq 0
 \end{aligned}$$

since $bd \neq 0 \neq b'd'$. Thus $+\mathbb{Q}$, $\cdot\mathbb{Q}$ and $\leq\mathbb{Q}$ are well-defined. \square

Proposition I.4.3. *The relation $\leq\mathbb{Q}$ is a total order on \mathbb{Q} .*

Proof. Transitivity: Suppose $(ad - bc)bd \leq 0$ and $(cf - de)df \leq 0$. Then $(adf - bcf)bdf \leq 0$ and $(bcf - bde)bdf \leq 0$. Adding these gives $(adf - bde)bdf \leq 0$ and so $(af - be)bf \leq 0$.

Antisymmetry: Suppose $(ad - bc)bd \leq 0$ and $(cb - da)db \leq 0$. Then $(ad - bc)bd = 0$ which gives $ad = bc$ so $x = y$. \square

Theorem I.4.4.

- $(\mathbb{Q}, +\mathbb{Q}, \cdot\mathbb{Q}, \leq\mathbb{Q})$ is an ordered field.
- The map $f = z \mapsto [z, 1]$ from \mathbb{Z} to \mathbb{Q} is an injective map that respects $+$, \cdot and \leq . That is, for all $z_1, z_2 \in \mathbb{Z}$,

- (i) $f(z_1 + z_2) = f(z_1) +_{\mathbb{Q}} f(z_2)$,
- (ii) $f(z_1 z_2) = f(z_1) \cdot_{\mathbb{Q}} f(z_2)$,
- (iii) $z_1 \leq z_2 \iff f(z_1) \leq_{\mathbb{Q}} f(z_2)$.

In other words, f is a commutative ring isomorphism into \mathbb{Q} .

Proof. For the first part, we check all ordered field axioms. We again omit the subscripts on $+$ and \cdot for brevity. Numbering is from UMA101.

(F1) $+$ and \cdot are commutative: immediate from commutativity of $+$ and \cdot on \mathbb{Z} .

(F2) $+$ and \cdot are associative:

$$\begin{aligned}
 ([a, b] + [c, d]) + [e, f] &= [ad + bc, bd] + [e, f] \\
 &= [(ad + bc)f + bde, bdf] \\
 &= [adf + b(cf + de), bdf] \\
 &= [a, b] + [cf + de, df] \\
 &= [a, b] + ([c, d] + [e, f])
 \end{aligned}$$

Associativity of \cdot is immediate from associativity on \mathbb{Z} .

(F3) Distributivity:

$$\begin{aligned}
 [a, b] \cdot ([c, d] + [e, f]) &= [a, b] \cdot [cf + de, df] \\
 &= [acf + ade, bdf] \\
 &= [abcf + abde, b^2df] \quad (b \text{ is nonzero}) \\
 &= [(ac)(bf) + (bd)(ae), (bd)(bf)] \\
 &= [ac, bd] + [ae, bf]
 \end{aligned}$$

(F4) Identities: $[0, 1] \neq [1, 1]$, $[a, b] + [0, 1] = [a, b]$ and $[a, b] \cdot [1, 1] = [a, b]$.

(F5) Additive inverse: $[a, b] + [-a, b] = [0, 1]$.

(F6) Multiplicative inverse: $[a, b] \cdot [b, a] = [1, 1]$ for $a \neq 0 \iff [a, b] \neq [0, 1]$.

For the second part,

$$(i) \quad f(z_1 + z_2) = [z_1 + z_2, 1] = [z_1, 1] + [z_2, 1].$$

$$(ii) \quad f(z_1 z_2) = [z_1 z_2, 1] = [z_1, 1] \cdot [z_2, 1].$$

$$(iii) \quad f(z_1) \leq f(z_2) \iff (z_1 - z_2) \leq 0 \iff z_1 \leq z_2. \quad \square$$

We now introduce the division operation $/ : \mathbb{Q} \times \mathbb{Q}^* \rightarrow \mathbb{Q}$ by $a/b = \frac{a}{b} = ab^{-1}$.

Notation. Note that every rational number $x = [a, b]$ can be written as $x = a/b$. We thus largely drop the notation $[a, b]$ and write a/b instead.

We will now accept basic algebraic manipulations of rational numbers without justification.

Definition I.4.5 (Exponentiation). The recursion principle guarantees the existence of $\text{pow} : \mathbb{Z} \times \mathbb{N} \rightarrow \mathbb{N}$ such that for all $n, m \in \mathbb{N}$,

$$\begin{aligned}\text{pow}(m, 0) &= 1 \\ \text{pow}(m, n + 1) &= m \cdot \text{pow}(m, n)\end{aligned}$$

We extend this to $\text{pow} : \mathbb{Q}^* \times \mathbb{Z} \rightarrow \mathbb{Q}$ as follows.

$$\text{pow}\left(\frac{a}{b}, m\right) := \begin{cases} a^m/b^m & \text{if } m \in \mathbb{N} \\ b^m/a^m & \text{if } -m \in \mathbb{N} \end{cases}$$

We write z^n to denote $\text{pow}(z, n)$.

Remark. Note that we have defined 0^0 to be 1, but we don't really care.

Proposition I.4.6. *Exponentiation is well-defined.*

Proof. Let $a/b = \tilde{a}/\tilde{b} \in \mathbb{Q}$. That is, $a\tilde{b} = b\tilde{a} \in \mathbb{Z}$. For $m \in \mathbb{N}$, thus $a^m\tilde{b}^m = b^m\tilde{a}^m$ (easily proved by induction).

Similarly if $-m \in \mathbb{N}$. □

Theorem I.4.7. *There is no rational whose square is 2.*

We first make note of the following lemma.

Lemma I.4.8. *Let $x \in \mathbb{Q}$. Then there exists $p \in \mathbb{Z}$, $q \in \mathbb{N}^*$ such that $x = p/q$. In particular, if $x > 0$, then $x = p/q$ for some $p \in \mathbb{N}$, $q \in \mathbb{N}^*$.*

Proof. Let $x = a/b$. If $b \in \mathbb{N}$, we are done. Otherwise, $x = -a/-b$ and $-b \in \mathbb{N}$. □

We will make use of the well-ordered property of (\mathbb{N}, \leq) proved below in theorem I.4.9.

Proof of theorem I.4.7. Suppose there exists such an x . By the field properties, $(-x)^2 = x^2$. Thus we may assume $x \geq 0$. Let $x = p/q$ for some $q \in \mathbb{N}^*$. Since $x \geq 0$, we have $p \geq 0 \iff p \in \mathbb{N}$.

Let $A = \{q \in \mathbb{N}^* \mid x = p/q \text{ for some } p \in \mathbb{N}\}$. A is non-empty.

By the well-ordering principle, A has a least element q_0 . Let $p_0 \in \mathbb{N}$ such that $x = p_0/q_0$.

We know that $1 < x < 2$ [why? because $(\cdot)^2$ is an increasing function on positive rationals (why? difference of squares)] and so $0 < p_0 - q_0 < q_0$. Now

$$\begin{aligned} \frac{2q_0 - p_0}{p_0 - q_0} &= \frac{2 - x}{x - 1} \\ &= \frac{(2 - x)(x + 1)}{x^2 - 1} \\ &= 2x + 2 - x^2 - x \\ &= x, \end{aligned}$$

in contradiction to the minimality of q_0 . □

Theorem I.4.9 (Well-ordering principle). *Every non-empty subset of \mathbb{N} has a least element.*

Proof. Let $S \subseteq \mathbb{N}$ be non-empty. We define $P(n)$ to be “if $n \in S$, then S has a least element”. Clearly $P(0)$ holds.

Suppose $P(k)$ holds for all $k \leq n \in \mathbb{N}$.

If $n + 1 \notin S$, $P(n + 1)$ holds vacuously.

If $\exists m \in S (m < n + 1)$, then $P(n + 1)$ holds by virtue of $P(m)$.

Otherwise $n + 1 \in S$ and $\forall m \in S (n + 1 \leq m)$, so that $n + 1$ is the least element of S .

In any case, $P(n + 1)$ holds. □

Theorem I.4.10. *Let*

$$A = \{x \in \mathbb{Q} \mid x^2 < 2\}$$

$$B = \{x \in \mathbb{Q} \mid x^2 > 2, x > 0\}$$

Then A has no largest element and B has no smallest element.

Proof. Let $a \in A$. $a > -2$ since otherwise $a^2 \geq 4$. Let $c = a + \frac{2-a^2}{2+a}$. Clearly

$c > a$. Now

$$\begin{aligned} c &= \frac{2a+2}{2+a} \\ c^2 &= \frac{4a^2+8a+4}{4+4a+a^2} \\ c^2-2 &= \frac{2a^2-4}{(2+a)^2} < 0 \end{aligned}$$

Thus $c \in A$.

For B , let $c = b + \frac{2-b^2}{2+b} = \frac{2b+2}{2+b}$. Clearly $0 < c < b$ and $c^2 - 2 = \frac{2b^2-4}{(2+b)^2} > 0$. Thus $c \in B$. \square

Corollary I.4.11. (\mathbb{Q}, \leq) does not have the least upper bound property.

Proof. Let b be an upper bound of A . Clearly $b > 0$. b cannot be in A since A has no largest element. b cannot have square 2 by theorem I.4.7. Thus $b \in B$. But since B has no smallest element, there is a $b' \in B$ which is less than b .

For any $a \in A$, if $a < 0$ then $a < b'$. Otherwise, $0 < (b')^2 - a^2 = (b' - a)(b' + a)$ and so $a < b'$. Thus b' is an upper bound of A which is less than b .

Since b was arbitrary, A cannot have a least upper bound. \square

I.5 Ordered Fields with LUB

(Recall from UMA101 Lecture 6) Given an ordered set (X, \leq) , a subset $S \subseteq X$ is said to be *bounded above* (resp. *below*) if there exists $x \in X$ such that for all $s \in S$, $s \leq x$ (resp. $x \leq s$), and any such x is called an *upper* (resp. *lower*) *bound* of S .

A (The) *supremum* or least upper bound of S is an element $x \in X$ such that x is an upper bound of S and for all upper bounds y of S , $x \leq y$. Similarly, *infimum* or greatest lower bound.

(X, \leq) is said to have the least upper bound property if every non-empty bounded above subset of X admits a supremum.

Theorem I.5.1. Every ordered field F “contains” \mathbb{Q} , i.e., there exists an injective map $f : \mathbb{Q} \rightarrow F$ that respects $+$, \cdot and \leq .

We will notate this statement as $\mathbb{Q} \subseteq F$.

Proof. Let $f : \mathbb{Z} \rightarrow F$ be defined as

$$f(n) = \begin{cases} 0_F & \text{if } n = 0 \\ \underbrace{1_F + \cdots + 1_F}_{n \text{ times}} & \text{if } n > 0 \\ \underbrace{(-1_F) + \cdots + (-1_F)}_{m \text{ times}} & \text{if } n = -m, m > 0 \end{cases}$$

Note that $f(-n) = -f(n)$ for all $n \in \mathbb{N}$. Let us show that $f(n+m) = f(n) + f(m)$ for all $n, m \in \mathbb{Z}$.

Case 1: $n = 0$ or $m = 0$. Immediate.

Case 2: $n > 0$ and $m > 0$. Then

$$\begin{aligned} f(n+m) &= \underbrace{1_F + \cdots + 1_F}_{n+m \text{ times}} \\ &= \underbrace{1_F + \cdots + 1_F}_{n \text{ times}} + \underbrace{1_F + \cdots + 1_F}_{m \text{ times}} \\ &= f(n) + f(m) \end{aligned}$$

Case 3: $n < 0$ and $m < 0$. Then $f(n+m) = -f((-n) + (-m)) = -(f(-n) + f(-m)) = f(n) + f(m)$.

Case 4: $nm < 0$. WLOG, let $m < 0 < n$. Suppose $0 < n+m$. Then $f(n+m) + f(-m) = f(n+m-m) = f(n)$ from case 2. Now suppose $n+m < 0$. Then $f(n) + f(-n-m) = f(n-n-m) = -f(m)$ from case 3. In either case, $f(n+m) = f(n) + f(m)$.

Now consider $f(nm)$. If $nm = 0$, then $f(nm) = 0_F = f(n)f(m)$. If $0 < n, m$,

then

$$\begin{aligned}
 f(nm) &= \overbrace{1_F + \cdots + 1_F}^{nm \text{ times}} \\
 &= \underbrace{\overbrace{(1_F + \cdots + 1_F)}^{n \text{ times}} + \cdots + \overbrace{(1_F + \cdots + 1_F)}^{n \text{ times}}}_{m \text{ times}} \\
 &= \underbrace{(1_F + \cdots + 1_F)}_{n \text{ times}} \cdot \underbrace{(1_F + \cdots + 1_F)}_{m \text{ times}} \\
 &= f(n)f(m)
 \end{aligned}$$

If either of n, m is negative, then we take the negative sign out and use the above case.

Thus f respects $+$ and \cdot .

Suppose that $m < n$. Then $f(n) - f(m) = f(n) + f(-m) = f(n - m) = (n - m)1_F$ (where $z1_F$ is notation for 1_F added z times). $n - m$ is positive, but 1_F added to itself a positive number of times must be positive. This is because $0_F < 1_F$ (UMA101) and so $k1_F < (k + 1)1_F$ for all $k \in \mathbb{N}^+$. Thus $f(m) < f(n)$ and so f respects $<$ (and hence \leq).

Finally, injectivity of f follows from order preservation.

We extend f to \mathbb{Q} by defining $f(a/b) = f(a)f(b)^{-1}$. This continues to be an isomorphism.

Why? First note that

$$f(ka/kb) = f(ka)f(kb)^{-1} = f(k)f(a)(f(k)f(b))^{-1} = f(a)f(b)^{-1} = f(a/b),$$

so that f is well-defined. Now

$$\begin{aligned}
 f(a/b + c/d) &= f\left(\frac{ad + bc}{bd}\right) \\
 &= f(ad + bc)f(bd)^{-1} \\
 &= (f(a)f(d) + f(b)f(c))(f(b)f(d))^{-1} \\
 &= f(a)f(b)^{-1} + f(c)f(d)^{-1} \\
 &= f(a/b) + f(c/d)
 \end{aligned}$$

and

$$\begin{aligned}
 f(a/b \cdot c/d) &= f(ac/bd) \\
 &= f(ac)f(bd)^{-1} \\
 &= f(a)f(b)^{-1}f(c)f(d)^{-1} \\
 &= f(a/b)f(c/d).
 \end{aligned}$$

Finally

$$\begin{aligned}
 f(a/b) \leq f(c/d) &\iff f(a)f(b)^{-1} \leq f(c)f(d)^{-1} \\
 &\iff f(a)f(b)f(d)^2 \leq f(c)f(d)f(b)^2 \\
 &\iff (f(ad) - f(bc))f(b)f(d) \leq 0 \\
 &\iff (ad - bc)bd \leq 0 \\
 &\iff a/b \leq c/d.
 \end{aligned}$$

Assignment 1

For quiz on 12
Jan 2024

Problem 1.1. Let $(\mathbb{Z}, +_{\mathbb{Z}}, \cdot_{\mathbb{Z}}, \leq_{\mathbb{Z}})$ be defined as in class. Recall that we identify $n \in \mathbb{N}$ with $[(n, 0)] \in \mathbb{Z}$. Show that any element of \mathbb{Z} is either m or $-m$ for some $m \in \mathbb{N}$.

Proof. Proved in proposition [I.3.8](#). □

Problem 1.2. Recall the construction of \mathbb{Q} as the set of equivalence classes of the relation R on $\mathbb{Z} \times \mathbb{Z} \setminus \{0\}$ given by $(a, b)R(c, d) \iff ad = bc$. We say that $[(a, b)] \leq [(c, d)]$ if $(bc - ad)(bd) \geq 0$. Using only the arithmetic and order properties of integers, show that the relation \leq is well-defined. Remember you are not allowed to divide yet!

Proof. Proposition [I.4.2](#). □

Problem 1.3. Without assuming the existence of irrational numbers, show that

- (a) (\mathbb{Z}, \leq) has the least upper bound property.
- (b) (\mathbb{Q}, \leq) does not have the least upper bound property.

You may directly cite any theorem(s) proved in class.

Proof.

- (a) Let S be a non-empty bounded above subset of \mathbb{Z} . Let b be an upper bound of S and let $f: \mathbb{Z} \rightarrow \mathbb{N}$ be as $f(x) = b - x$. By the well-ordering principle, $f(S)$ has a least element m . Then $b - m$ is the maximum of S .
- (b) Corollary [I.4.11](#). □

Problem 1.4. Let F be an ordered field. Recall that $\mathbb{Q} \subseteq F$. Show that the following two statements are equivalent.

- (i) For every $a, b > 0$ in F , there is an $n \in \mathbb{N}$ such that $na > b$.
- (ii) For every $a < b$ in F , there is an $r \in \mathbb{Q}$ such that $a < r < b$.

Proof. Suppose item (i) holds. Let $a < b$ in F . Then $1/(b-a) > 0$. Let $n \in \mathbb{N}$ be such that $n > 1/(b-a)$, i.e., $1/n < b-a$. We first show that there is a rational at most a . If $a \geq 0$, this is trivial. Otherwise, $-a > 0$ and so by item (i), there is an $m \in \mathbb{N}$ such that $m > 1/(-a) \iff -1/m < a$. Thus the set $S = \{k \in \mathbb{Z} \mid k \cdot \frac{1}{n} \leq a\}$ is non-empty. By item (i), it is bounded above. By problem 1.3(a), it has a maximum M . Then $\frac{M}{n} \leq a < \frac{M+1}{n} \leq a + \frac{1}{n} < b$. Thus $\frac{M+1}{n}$ is the required rational.

Suppose item (ii) holds. Let $0 < a, b$. Then there exist $p \in \mathbb{N}$ and $q \in \mathbb{N}^*$ such that $0 < b/a < p/q < b/a + 1$. Since $1 \leq q$, $p/q \leq p$. Then $b < pa$ as required. \square

Problem 1.5. Let F be a field. An absolute value of F is a function $A: F \rightarrow \mathbb{R}$ satisfying

- (1) $A(x) \geq 0$ for all $x \in F$,
- (2) $A(x) = 0$ if and only if $x = 0$,
- (3) $A(xy) = A(x)A(y)$ for all $x, y \in F$,
- (4) $A(x + y) \leq A(x) + A(y)$ for all $x, y \in F$.

A subset $S \subseteq F$ is said to be A -bounded if there exists an $M > 0$ such that $A(s) \leq M$ for all $s \in S$. This is a way to define boundedness of sets in the absence of an order relation.

Let $p \in \mathbb{N}$ be a prime number. Define $\nu_p: \mathbb{Z} \rightarrow \mathbb{Z} \cup \{\infty\}$ by

$$\nu_p(n) = \begin{cases} \max\{k \in \mathbb{N} : p^k \mid n\}, & \text{if } n \neq 0, \\ \infty, & \text{if } n = 0. \end{cases}$$

Extend ν_p to \mathbb{Q} by

$$\nu_p(a/b) = \nu_p(a) - \nu_p(b), \quad a, b \in \mathbb{Z}, b \neq 0.$$

Now, define $A_p: \mathbb{Q} \rightarrow \mathbb{R}$ by $A_p(x) = e^{-\nu_p(x)}$ if $x \neq 0$, and $A_p(0) = 0$.

- (a) Show that A_p is an absolute value on \mathbb{Q} .
- (b) Show that

$$A_p(x + y) \leq \max\{A_p(x), A_p(y)\}, \quad x, y \in \mathbb{Q}.$$

- (c) Show that \mathbb{Z} is A_p -bounded.

You may use basic facts about factorization without proof, but clearly state what you are using.

Proof. A_p satisfies (1) and (2) by definition.

Let $x = a/b$, $y = c/d$ in \mathbb{Q} . If either is zero, (3) holds trivially. Otherwise $xy = ac/bd$ with $a, b, c, d \in \mathbb{Z}^*$. Let $a = p^{\nu_p(a)}a'$, $c = p^{\nu_p(c)}c'$, where a', c' are coprime to p . Then $ac = p^{\nu_p(a)+\nu_p(c)}(a'c')$. Thus $\nu_p(ac) = \nu_p(a) + \nu_p(c)$. Similarly, $\nu_p(bd) = \nu_p(b) + \nu_p(d)$. Thus $\nu_p(xy) = \nu_p(x) + \nu_p(y)$ and so $A_p(xy) = A_p(x)A_p(y)$.

(4) follows from (b), which we prove now. If either x or y is zero, (b) holds trivially. Let

$$x = \frac{p^\alpha a}{p^\beta b}, \quad y = \frac{p^\gamma c}{p^\delta d},$$

where $a, b, c, d \in \mathbb{Z}^*$ are coprime to p . Thus $\nu_p(x) = \alpha - \beta$ and $\nu_p(y) = \gamma - \delta$. WLOG suppose that $A_p(x) \geq A_p(y) \iff \nu_p(x) \leq \nu_p(y)$ which gives $\alpha - \beta \leq \gamma - \delta$.

$$\begin{aligned} x + y &= \frac{p^{\alpha+\delta}ad + p^{\beta+\gamma}bc}{p^{\beta+\delta}bd} \\ &= \frac{p^{\alpha+\delta}(ad + p^{\beta+\gamma-\alpha-\delta}bc)}{p^{\beta+\delta}bd} \end{aligned}$$

Thus $\nu_p(x + y) \geq \alpha + \delta - \beta - \delta = \alpha - \beta$ and so $A_p(x + y) \leq A_p(x) = \max\{A_p(x), A_p(y)\}$.

(c) follows from $\nu_p(x) \geq 0$, so that $A_p(x) \leq 1$ for all $x \in \mathbb{Z}$. \square

Lecture 4.

Definition I.5.2 (Archimedean property). An ordered field F is said to have the *Archimedean property* if for every $x, y > 0$, there exists an $n \in \mathbb{N} \subseteq F$ such that $nx > y$.

Theorem I.5.3. \mathbb{Q} has the Archimedean property.

Proof. Let $x, y > 0$ be rationals. If $x > y$, $n = 1$ works. Suppose $x \leq y$. It suffices to show that $\exists n \in \mathbb{N}(nr > 1)$, where $r = x/y$. Since r is positive, we have $p, q \in \mathbb{N}^*$ such that $r = p/q$. Let $n = 2q$. This gives $nr > 1$. \square

Remark. Not all ordered fields have the Archimedean property.

Theorem I.5.4. Let F be an ordered field with the LUB property. Then F has the Archimedean property.

Proof. Let $x, y > 0$. Suppose $\forall n \in \mathbb{N}(nx \leq y)$. Let $A = \{nx \mid n \in \mathbb{N}\}$. Clearly A is non-empty and bounded above. Then $\sup A$ exists and so there exists an $m \in \mathbb{N}$ such that $\sup A - x < mx$. Thus $\sup A < (m + 1)x \in A$, a contradiction. \square

Theorem I.5.5. Let F be an ordered field with the LUB property. Then \mathbb{Q} is dense in F , i.e., given $x < y \in F$, there exists a rational $r \in \mathbb{Q}$ such that $x < r < y$.

Proof. Follows from theorem I.5.3 and problem 4 on assignment 1. \square

I.6 The Reals

Theorem I.6.1 (Dedekind/Cauchy). There exists a unique (up to isomorphism) ordered field with the LUB property.

We first recover some properties of supremums.

Lemma I.6.2. *Let F be an ordered field with the LUB property. Let A and B be non-empty bounded above subsets of F . Then $\sup A + \sup B = \sup(A + B)$. Further, if all elements of A and B are non-negative, then $\sup A \sup B = \sup(AB)$.*

Here $A + B := \{a + b \mid a \in A, b \in B\}$ and $AB := \{ab \mid a \in A, b \in B\}$.

Proof. Let $\alpha = \sup A$ and $\beta = \sup B$. For all $a \in A$ and $b \in B$, $a + b \leq \alpha + \beta$. Thus $\alpha + \beta$ is an upper bound of $A + B$.

Let $c < \alpha + \beta$. Since $c - \beta < \alpha$, there exists an $a \in A$ larger than $c - \beta$. Then $c - a < \beta$ and so there exists a $b \in B$ larger than $c - a$. Thus $c < a + b \in A + B$ and so $\alpha + \beta = \sup(A + B)$.

Now suppose all elements of A and B are non-negative. If $\alpha = 0$ or $\beta = 0$, then $\alpha\beta = 0$ and so $\alpha\beta = \sup(AB)$.

For all $a \in A$ and $b \in B$, $ab \leq \alpha\beta$. Let $c < \alpha\beta$. Since $c/\beta < \alpha$, there exists an $a \in A$ larger than c/β . Then $c/a < \beta$ and so there exists a $b \in B$ larger than c/a . Thus $c < ab \in AB$ and so $\alpha\beta = \sup(AB)$. \square

Proof of uniqueness. Let F and G be OFWLUB. Let h be identity on $\mathbb{Q} \subseteq F, G$. For $z \in F$ let

$$A_z = \{w \in \mathbb{Q} \mid w <_F z\}.$$

Claim: A_z is non-empty and bounded above when viewed as a subset of G , and therefore has a supremum in G .

First, A_z is non-empty by density applied to $(z - 1_F, z)$ or Archimedean applied to $-z$. Secondly, by Archimedean (or density) there exists a rational upper bound q of A_z in F . This q is also an upper bound of A_z in G .

By LUB, A_z has a supremum in G .

We define $h(z) := \sup_G A_z$. For this we need to show that $h(r) = r$ for all $r \in \mathbb{Q}$, so that the definitions coincide. Let $r \in \mathbb{Q}$ so that $A_r = \{w \in \mathbb{Q} \mid w <_F r\}$. Clearly r is an upper bound of A_r in G . For any $g \in G$ less than r , there is some $q \in \mathbb{Q}$ such that $g <_G q <_G r$ (by density of \mathbb{Q} in G). Thus g cannot be an upper bound of $A_r \subseteq G$. Thus $r = \sup_G A_r = h(r)$.

Claim: h preserves order.

Let $z < w \in F$. By density of \mathbb{Q} in F , there exist rationals r, s, t such that $z < r < s < w$. Then $A_z \subsetneq A_w$ as subsets of F and hence of G . Thus

$$h(z) = \sup_G A_z \leq_G r < s \leq_G \sup_G A_w = h(w).$$

Claim: h preserves addition.

It is sufficient to show that $A_{x+y} = A_x + A_y$, where set addition is defined pairwise. If a rational $q \in A_x + A_y$, then clearly $q <_F x + y$ and so $q \in A_{x+y}$. Let $q \in A_{x+y} \iff q <_F x + y$. Then $q - x \in A_y$. Since A_y has no largest element (by density), there exists an $r \in A_y$ with $q - x < r < y$. Then $q - r < x$ and so $q - r \in A_x$. Thus $q = (q - r) + r \in A_x + A_y$ which gives equality of the sets.

From the previous lemma, $\sup A_x + \sup A_y = \sup(A_x + A_y) = \sup A_{x+y}$ and so h preserves addition.

Claim: h preserves multiplication.

Let $0 < x, y \in F$. Let $A_z^+ = \{w \in \mathbb{Q} \mid 0 < w <_F z\}$. We will show that $A_{xy}^+ = A_x^+ A_y^+$, where set product is defined pairwise. If a rational $q \in A_{xy}^+$, then clearly $0 < q <_F xy$ and so $q \in A_{xy}^+$. Let $q \in A_{xy}^+ \iff 0 < q <_F xy$. Then $q/x \in A_y^+$. Since A_y^+ has no largest element, there exists an $r \in A_y^+$ with $q/x < r < y$. Then $q/r < x$ and so $q/r \in A_x^+$. Thus $q = (q/r) \cdot r \in A_x^+ A_y^+$ which gives equality of the sets.

From the previous lemma, $\sup A_x^+ \sup A_y^+ = \sup(A_x^+ A_y^+) = \sup A_{xy}^+$ and so h preserves multiplication of positive elements.

Since h preserves addition, h preserves additive inverses. So h preserves multiplication of all elements.

Thus h is an isomorphism between F and G . □

I.6.1 Dedekind's Construction

Definition I.6.3 (Dedekind cut). A *Dedekind cut* is a non-empty proper subset $A \subsetneq \mathbb{Q}$ such that

- (i) if $a \in A$, then $b \in A$ for all $b \in \mathbb{Q}$ with $b < a$.
- (ii) if $a \in A$, then there exists a $c \in A$ such that $a < c$.

Definition I.6.4 (\mathbb{R}). We define

$$\mathbb{R} := \{A \in 2^{\mathbb{Q}} \mid A \text{ is a Dedekind cut}\}.$$

Further,

- (i) $A \leq B \iff A \subseteq B$;
- (ii) $A + B = \{a + b \mid a \in A, b \in B\}$.
- (iii) for $A, B > 0$,

$$A \cdot B = \{q \in \mathbb{Q} \mid q \leq rs \text{ for some } r \in A, s \in B\}.$$

If $A < 0$ but $B > 0$, then $A \cdot B = -((-A) \cdot B)$. If $B < 0$ but $A > 0$, then $A \cdot B = -(A \cdot (-B))$. If $A < 0$ and $B < 0$, then $A \cdot B = (-A) \cdot (-B)$.

Proposition I.6.5. $O = \{z \in \mathbb{Q} \mid z < 0\}$ is the additive identity of \mathbb{R} . For any $A \in \mathbb{R}$,

$$B = \{x \in \mathbb{Q} \mid \exists r \in O (r - x \notin A)\}$$

is an additive inverse of A .

Proof. Let $A \in \mathbb{R}$. For all $a \in A$, there exists $a' \in A$ larger than a . So $a - a' \in O$ and thus $a' + (a - a') = a \in A + O$.

For all $a \in A + O$, there exists $a' \in A$ and $o \in O$ such that $a = a' + o$. But then $a' > a$, so $a \in A$. Thus $A + O = A$.

Let B be as defined. Let $a + b \in A + B$ where $a \in A$ and $b \in B$. Then there exists $r \in O$ such that $r - b \notin A$. So $r - b > a$ and thus $a + b < r < 0$.

Now let $o \in O$. Since O has no largest element, there exists an $o' \in O$ such that $o' > o$. Let $a \in A$. Consider the set $\alpha = \{n \in \mathbb{Z} \mid a + n(o' - o) \in A\}$. By archimedean property of \mathbb{Q} , α is bounded. It is obviously non-empty. Thus it has a supremum n . Let $a' = a + n(o' - o)$. $a' + (o' - o) = o' - (o - a') \notin A$ because n was supremum. This gives $o - a' \in B$. Thus $o \in A + B$. \square

Theorem I.6.6. \mathbb{R} has the least upper bound property.

Proof. Let α be a non-empty subset of \mathbb{R} that is bounded above. We claim that $S = \bigcup_{A \in \alpha} A$ is the supremum of α .

Lecture 5.

Thursday

January 11

s is a cut: Since S is a union of a non-empty set of non-empty sets, it is non-empty. Since S is bounded above, say by some cut C , we have $S \subseteq C \subsetneq \mathbb{Q}$ and so $S \neq \mathbb{Q}$. If $a \in S$, then $a \in A$ for some $A \in \alpha$. Since A is a cut, every rational smaller than a is contained in A and thereby in S . Moreover, there exists an $a' \in A$ which is larger than a . Thus $a' \in S$ is larger than a .

upper bound: $A \subseteq S$ for all $A \in \alpha$.

least upper bound: For any $D \subsetneq S$, let $b \in S \setminus D$. But since $b \in A$ for some $A \in \alpha$, D is not an upper bound of α . \square

Dedekind's construction is an "order completion". Thus all the order properties (LUB, density) are nice, but arithmetic is ugly.

I.6.2 Cauchy's Construction

There seem to be sequences in \mathbb{Q} that "should" have a limit (*e.g.*, a monotone and bounded sequence) but do not (within \mathbb{Q}). We construct equivalence classes of sequences which "converge" to the same number, and define reals by those classes.

Definition I.6.7 (Sequence). A sequence of rational numbers is a $f: \mathbb{N} \rightarrow \mathbb{Q}$. We usually denote $f(k)$ by a_k and call it the k -th term of the sequence. The function f is usually written as $(a_k)_{k \in \mathbb{N}}$.

Definition I.6.8. A sequence $(a_k)_{k \in \mathbb{N}} \subseteq \mathbb{Q}$ is said to be

- (i) \mathbb{Q} -bounded if there exists an $M \in \mathbb{Q}$ such that $|a_k| \leq M$ for all $k \in \mathbb{N}$.
- (ii) \mathbb{Q} -Cauchy if for every rational $\epsilon > 0$, there exists an $N \in \mathbb{N}$ such that $|a_m - a_n| < \epsilon$ for all $m, n \geq N$.
- (iii) convergent in \mathbb{Q} if there exists an $L \in \mathbb{Q}$ such that for all (rational) $\epsilon > 0$, there exists an $N \in \mathbb{N}$ such that $|a_n - L| < \epsilon$ for all $n \geq N$.

Exercise I.6.9. Show that if a sequence is convergent in \mathbb{Q} , then it is \mathbb{Q} -Cauchy, and if it is \mathbb{Q} -Cauchy, then it is \mathbb{Q} -bounded.

Remark. From UMA101, we know that if a sequence is convergent in \mathbb{Q} , the limit is unique. We also know arithmetic laws of limits (which we proved over \mathbb{R} , but they hold over \mathbb{Q} as well).

Definition I.6.10. Two sequences $a = (a_n)_{n \in \mathbb{N}}$ and $b = (b_n)_{n \in \mathbb{N}}$ are said to be *equivalent* if their difference converges to 0.

Proposition I.6.11. Let \mathcal{C} denote the space of \mathbb{Q} -cauchy sequences. Then \sim given by $a \sim b$ if a and b are equivalent (as per the previous definition) is an equivalence relation.

Proof. Reflexivity and symmetry are immediate. Transitivity follows from the triangle inequality. \square

Definition I.6.12 (\mathbb{R}). We define

$$\mathbb{R} := \mathcal{C} / \sim.$$

Further,

- (i) $[(a_n)_n] +_{\mathbb{R}} [(b_n)_n] := [(a_n + b_n)_n]$.
- (ii) The additive identity $0 = [(0)_{n \in \mathbb{N}}]$.
- (iii) $[(a_n)_n] \cdot_{\mathbb{R}} [(a_n)_n] := [(a_n \cdot b_n)_n]$.
- (iv) $[a]$ is positive iff there exists a rational $c > 0$ and an $N \in \mathbb{N}$ such that $a_n > c$ for all $n \geq N$.

Recall how we define order from a set of positive elements. Assuming the existence of additive inverses, we define $a <_R b$ iff $b - a$ is positive. The set of positive elements \mathbb{R}^+ must satisfy (Apostol order axioms):

- $0 \notin \mathbb{R}^+$.
- For $x \neq 0$, exactly one of $x \in \mathbb{R}^+$ or $-x \in \mathbb{R}^+$ holds.
- For $x, y \in \mathbb{R}^+$, $x + y \in \mathbb{R}^+$ and $x \cdot y \in \mathbb{R}^+$.

The first two give trichotomy, and the third is the field order properties.

Proposition I.6.13. *The operations $+\mathbb{R}$ and $\cdot_{\mathbb{R}}$ and the relation $>_{\mathbb{R}}$ are well-defined.*

Proof. Let $a \sim a'$ and $b \sim b'$ be \mathbb{Q} -Cauchy sequences. Then $(a+b) - (a'+b') = (a-a') + (b-b') \rightarrow 0$. So $a+b \sim a'+b'$.

For multiplication,

$$\begin{aligned} ab - a'b' &= ab - ab' + ab' - a'b' \\ &= a(b-b') + b'(a-a') \\ &\rightarrow 0. \end{aligned}$$

So $ab \sim a'b'$.

Finally, for any positive c , $a_n - a'_n$ is eventually smaller than $c/2$, so $a_n > c$ implies $a'_n > c/2$ for sufficiently large n . \square

Proposition I.6.14. *The relation $<_{\mathbb{R}}$ makes \mathbb{R} an ordered field.*

Proof. First note that each $[x] \in \mathbb{R}$ has additive inverse $[-x]$ where each term is the additive inverse of the corresponding term in x .

$[0] \notin \mathbb{R}^+$ is obvious.

Let $[x] \neq 0$. Suppose $[x] \in \mathbb{R}^+$ and $-[x] \in \mathbb{R}^+$. Then there exists $c, d > 0$ and $N \in \mathbb{N}$ such that $x_n > c$ and $-x_n > d$ for all $n \geq N$. This is a contradiction.

Now suppose neither is positive. Then for any $\varepsilon > 0$, there exists an $N \in \mathbb{N}$ such that $x_n < \varepsilon$ and $-x_n < \varepsilon$ for all $n \geq N$. But this means that $x_n \rightarrow 0$ so $[x] = 0$, a contradiction.

Finally, let $[x], [y] \in \mathbb{R}^+$. Then for c, d bounding x and y , we have $x_n + y_n > c + d$ for sufficiently large n . Similarly, $x_n y_n > cd$ for the same n . \square

Assignment 2

For quiz on 19
Jan 2024

Problem 2.1. Let F and G be ordered fields with the LUB property. In Lecture 04, we defined $h: F \rightarrow G$ as

$$h(z) = \sup_G \{w \in \mathbb{Q} : w \leq z\}.$$

Show that h is a field isomorphism, *i.e.*,

- (1) h is a bijection between F and G ,
- (2) $h(x + y) = h(x) + h(y)$ for all $x, y \in F$,
- (3) $h(x \cdot y) = h(x) \cdot h(y)$ for all $x, y \in F$.

Proof. Theorem [I.6.1](#). □

Problem 2.2. In this problem, you may assume the well-definedness, commutativity and associativity of addition of Dedekind cuts (as defined in Lecture 04). Let $O = \{z \in \mathbb{Q} : z < 0\}$. Verify that O is a Dedekind cut, and $A + O = A$ for all Dedekind cuts A . Let A be a Dedekind cut. Define a Dedekind cut B such that $A + B = O$. You must justify your answer.

Proof. Proposition [I.6.5](#). □

Problem 2.3. Let $a = (a_n)_{n \in \mathbb{N}}$ and $b = (b_n)_{n \in \mathbb{N}}$ be sequences of rational numbers such that $b_n \neq 0$ for all $n \in \mathbb{N}$. Suppose

$$\lim_{n \rightarrow \infty} \frac{a_n}{b_n} = 1.$$

- (i) Are a and b equivalent?
- (ii) Are a and b equivalent if a is a \mathbb{Q} -bounded sequence?

Solution.

- (i) No. $a_n = n + 1$ and $b_n = n$ gives a counterexample.

(ii) Yes.

Let a be bounded by M . Let n_0 be such that for all $n \geq n_0$, $\frac{1}{2} < \frac{a_n}{b_n}$. Then, for all $n \geq n_0$, $|b_n| < 2|a_n| \leq 2M$. Thus b is bounded.

Let $\varepsilon > 0$. Let N be such that for all $n \geq N$,

$$\left| \frac{a_n}{b_n} - 1 \right| < \frac{\varepsilon}{2M}.$$

Then for all $n \geq N$,

$$\begin{aligned} |a_n - b_n| &= |b_n| \left| \frac{a_n}{b_n} - 1 \right| \\ &< 2M \frac{\varepsilon}{2M} \\ &= \varepsilon. \end{aligned}$$

■

Problem 2.4. You cannot use the existence (or the LUB property) of the ordered field of real numbers in this problem, so you must work “within” \mathbb{Q} .

- (1) Show that every monotone \mathbb{Q} -bounded monotone sequence of rational numbers is \mathbb{Q} -Cauchy.
- (2) Consider the following sequence:

$$x_n = \begin{cases} 2, & \text{if } n = 0, \\ x_{n-1} - \frac{x_{n-1}^2 - 2}{2x_{n-1}} & \text{if } n \geq 1. \end{cases}$$

Confirm that $(x_n)_{n \in \mathbb{N}}$ is well-defined, *i.e.*, $x_n \neq 0$ for all $n \in \mathbb{N}$. Show that $(x_n)_{n \in \mathbb{N}}$ is \mathbb{Q} -Cauchy, but not convergent in \mathbb{Q} .

Solution. (1) Let $(x_n)_{n \in \mathbb{N}}$ be a monotone \mathbb{Q} -bounded sequence. WLOG assume that it is increasing.

Let $\varepsilon > 0$. Let

$$N = \inf\{n \in \mathbb{Z} \mid n\varepsilon \text{ is an upper bound of } (x_n)_n\}.$$

Why is the set non-empty? There is an upper bound b for $\{x_n\}_n$. Archimedeanly, there is an $n_0 : n_0\varepsilon > b$. Then n_0 belongs to the set.

Why is it bounded below? Archimedeanly, there is an $n_1 : n_1\varepsilon < x_0$. Then n_1 is a lower bound of the set.

Thus $N\varepsilon$ is an upper bound, but $(N-1)\varepsilon$ is not. So there exists some M such that $x_M > (N-1)\varepsilon$. Then for all $n \geq M$, $(N-1)\varepsilon < x_n \leq N\varepsilon$. So for any $n \geq m \geq M$,

$$|x_n - x_m| = x_n - x_m < N\varepsilon - (N-1)\varepsilon = \varepsilon.$$

(2)

$$\begin{aligned} x_n &= \frac{x_{n-1}^2 + 2}{2x_{n-1}} & (*) \\ \implies x_n^2 - 2 &= \frac{x_{n-1}^4 + 4x_{n-1}^2 + 4 - 8x_{n-1}^2}{4x_{n-1}^2} \\ &= \frac{(x_{n-1}^2 - 2)^2}{4x_{n-1}^2} \end{aligned}$$

This shows that $x_n^2 > 2$ for all $n \in \mathbb{N}$. From $(*)$, $x_{n-1} > 0$ implies $x_n > 0$, so $(x_n)_n > 0$. Thus

$$x_n - x_{n-1} = -\frac{x_{n-1}^2 - 2}{2x_{n-1}} < 0$$

and so $(x_n)_n$ is decreasing.

From the first part, $(x_n)_n$ is \mathbb{Q} -Cauchy. But suppose it had a limit $x \in \mathbb{Q}$. Note that $x \neq 0$, since $x_n^2 > 2$. Then

$$x = x - \frac{x^2 - 2}{2x} \implies x^2 = 2,$$

which is not possible. ■

Problem 2.5. A *digit* is any element of the set $S = \{0, 1, \dots, 9\}$. An *admissible sequence of digits* is a sequence $(a_n)_{n \in \mathbb{N}^*} \subseteq S$ satisfying the property: there is no $N \geq 1$ such that $a_n = 9$ for all $n \geq N$. Given $x \in [0, 1)$, we say that an admissible sequence of digits $(d_n)_{n \in \mathbb{N}^*}$ is a *decimal representation* of x if

$$\sup \left\{ D_n := \sum_{j=1}^n \frac{d_j}{10^j} \mid n \in \mathbb{N} \right\} = x.$$

Show that every admissible sequence of digits is the decimal representation of a number $x \in [0, 1)$, and conversely, every $x \in [0, 1)$ admits a unique decimal representation defined as above.

Note: In this problem, you may freely use the standard properties of real numbers.

Solution. Let $(d_n)_n$ be an admissible sequence of digits. Note that the given set is non-empty, and bounded above by $\sum_{j=1}^n \frac{9}{10^j} = 1$. Thus the supremum exists. It is obviously non-negative.

Why is it less than 1? Let i be the first index where $d_i \neq 9$. Then for each $n \geq i$,

$$\begin{aligned} \sum_{j=1}^n \frac{d_j}{10^j} &= \sum_{j=1}^{i-1} \frac{d_j}{10^j} + \frac{d_i}{10^i} + \sum_{j=i+1}^n \frac{d_j}{10^j} \\ &\leq \sum_{j=1}^{i-1} \frac{d_j}{10^j} + \frac{d_i}{10^i} + \sum_{j=i+1}^n \frac{9}{10^j} \\ &= \sum_{j=1}^{i-1} \frac{d_j}{10^j} + \frac{d_i + 1}{10^i} \\ &\leq \sum_{j=1}^{i-1} \frac{d_j}{10^j} + \frac{9}{10^i} < 1. \end{aligned}$$

Of course, for each $n < i$, the inequality still holds. Thus $\sum_{j=1}^i \frac{d_j}{10^j} + \frac{1}{10^i}$ is an upper bound less than 1.

For the converse, let $d_0 = 0$. For each $n \in \mathbb{N}^*$, let

$$d_n = \max \left\{ d \in S \mid D_{n-1} + \frac{d}{10^n} \leq x \right\},$$

where $D_{n-1} = \sum_{j=1}^{n-1} \frac{d_j}{10^j}$. This ensures that $D_n \leq x < D_n + 10^{-n}$ for each n . How? Holds trivially for $n = 0$. If it holds for $n - 1$, then d_n is chosen such that

$$D_n \leq x < D_n + \frac{1}{10^n},$$

if $d_n \neq 9$. But if $d_n = 9$, then $D_n \leq x < D_{n-1} + 10^{-n+1} = D_n + 10^{-n}$. Thus it holds for all n .

Then x is an upper bound for $(D_n)_n$. Suppose there is a lesser upper bound s . Then there exists n such that $10^{-n} < x - s$. But then $x < D_n + 10^{-n} < D_n + x - s$ so $s < D_n$. Thus $\sup_n D_n = x$.

For uniqueness, let $(d_n)_n$ and $(d'_n)_n$ be two distinct admissible sequences of digits. Suppose they first differ at the index j , with $d_j < d'_j$, and that $d_k \neq 9$ with $k \geq j$. Then for $n \geq k$,

$$\begin{aligned} D_n &= D'_{j-1} + \frac{d_j}{10^j} + \sum_{i=j+1}^n \frac{d_i}{10^i} \\ &\leq D'_{j-1} + \frac{d'_j - 1}{10^j} + \sum_{i=j+1}^n \frac{d_i}{10^i} \\ &\leq D'_{j-1} + \frac{d'_j - 1}{10^j} + \sum_{i=j+1}^n \frac{9}{10^i} - \frac{1}{10^k} \\ &= D'_{j-1} + \frac{d'_j}{10^j} - \frac{1}{10^k} - \frac{1}{10^n} \\ &< D'_j - \frac{1}{10^k}. \end{aligned}$$

Thus $\{D_n\}$ is bounded above by $\sup_n D'_n - 10^{-k}$. So $\sup_n D_n < \sup_n D'_n$. ■

We define an isomorphism from \mathbb{Q} into \mathbb{R} as

$$r \in \mathbb{Q} \mapsto [(r, r, \dots)] \in \mathbb{R}.$$

The proof is direct.

Theorem I.6.15. $(\mathbb{R}, +, \cdot, \leq)$ satisfies the Archimedean property.

Proof. Let $[a], [b] > 0$ be in \mathbb{R} . Since $[b]$ is \mathbb{Q} -Cauchy, there exists a positive $M \in \mathbb{Q}$ such that $b_n < M$ for all $n \in \mathbb{N}$.

Since $[a] > 0$, let $c \in \mathbb{Q}^+$ and $N \in \mathbb{N}$ be such that $a_n > c$ for all $n \geq N$. By the Archimedean property of \mathbb{Q} , there exists an $m \in \mathbb{N}$ such that $mc > M$. Thus $b_n < M < mc < ma_n$ for all $n \geq N$. Thus $(m+1)a_n - b_n > ma_n - b_n + c > c$ for all $n \geq N$ and so $[m+1][a] > [b]$. \square

Theorem I.6.16. $(\mathbb{R}, +, \cdot, \leq)$ satisfies the LUB property.

Proof. Let $A \subseteq \mathbb{R}$ be a non-empty bounded above set.

For $n \in \mathbb{N}^*$, let

$$U_n = \left\{ m \in \mathbb{Z} : \frac{m}{n} \text{ is an upper bound of } A \right\}.$$

From the Archimedean property of \mathbb{R} , U_n is non-empty and bounded below. By well-ordering, U_n has a minimum $m(n)$. Let $a_n = \frac{m(n)}{n}$ for each $n \in \mathbb{N}^*$.

Claim: $(a_n)_{n \in \mathbb{N}^*}$ is \mathbb{Q} -Cauchy.

Let ε be a positive rational number. By Archimedean, $\frac{1}{n} < \varepsilon$ for all n above some N in \mathbb{N} . Note that for any $n \in \mathbb{N}^*$, a_n is an upper bound of A , and $a_n - \frac{1}{n}$ is not an upper bound of A .

Thus for any $n, n' \geq N^*$, we have

$$\begin{aligned} \frac{m(n)}{n} &> \frac{m(n')}{n'} - \frac{1}{n'} & \frac{m(n')}{n'} &> \frac{m(n)}{n} - \frac{1}{n} \\ a_n - a_{n'} &> -\frac{1}{n'} & a_n - a_{n'} &< \frac{1}{n} \end{aligned}$$

and so $|a_n - a_{n'}| < \max\left\{\frac{1}{n}, \frac{1}{n'}\right\} < \varepsilon$.

Claim: $[(a_n)]$ is an upper bound of A .

Suppose there exists some $[x] > [a]$. That is, there is some positive rational

Lecture 6.

Monday

January 15

c such that $c < x_n - a_n$ for all n larger than some $N_1 \in \mathbb{N}^*$. Since (x_n) is \mathbb{Q} -Cauchy, $-c/2 < x_n - x_m < c/2$ for all n, m larger than some $N_2 \in \mathbb{N}^*$. \square

I.7 The Complex Numbers

Definition I.7.1. A *complex number* is an ordered pair of real numbers. We define operations on the set \mathbb{C} of complex numbers as follows.

Lecture 7.

Wednesday

January 17

$$\begin{aligned}(a, b) + (c, d) &= (a + c, b + d) \\ (a, b) \cdot (c, d) &= (ac - bd, ad + bc) \\ |(a, b)| &= \sqrt{a^2 + b^2}\end{aligned}$$

We further define i to be $(0, 1)$.

Remark. These operations make \mathbb{C} a *normed field*.

Theorem I.7.2. The map $f: \mathbb{R} \rightarrow \mathbb{C}$ given by $f(x) = (x, 0)$ is an isomorphism into \mathbb{C} .

This allows us to identify $x \in \mathbb{R}$ with $(x, 0) \in \mathbb{C}$.

Remark. $(a, b) = a + ib$ for any $a, b \in \mathbb{R}$. $i^2 = -1$.

0 is the additive identity and $(-a) + i(-b)$ is the additive inverse of $a + ib$.

1 is the multiplicative identity and for $a + ib \neq 0$, $\frac{a}{a^2+b^2} + i\frac{-b}{a^2+b^2}$ is the multiplicative inverse of (a, b) .

Theorem I.7.3 (Cauchy-Schwarz inequality). Let a_1, \dots, a_n and b_1, \dots, b_n be complex numbers. Then

$$\left| \sum_{j=1}^n a_j \overline{b_j} \right|^2 \leq \left(\sum_{j=1}^n |a_j|^2 \right) \left(\sum_{j=1}^n |b_j|^2 \right).$$

Proof. Let $\lambda = u + iv \in \mathbb{C}$.

$$\begin{aligned}0 &\leq \sum_{j=1}^n (a_j + \lambda b_j) \overline{(a_j + \lambda b_j)} \\ &= \sum_{j=1}^n (a_j \overline{a_j} + \overline{\lambda} a_j \overline{b_j} + \lambda b_j \overline{a_j} + |\lambda|^2 b_j \overline{b_j}) \\ &= \sum_{j=1}^n |a_j|^2 + 2[u \operatorname{Re}(A) + v \operatorname{Im}(A)] + (u^2 + v^2)B\end{aligned}$$

where $A = \sum_{j=1}^n a_j \overline{b_j}$ and $B = \sum_{j=1}^n |b_j|^2$.

Let the right hand expression be $F(u, v)$. Then $F_u(u, v) = 2 \operatorname{Re}(A) + 2uB$ and $F_v(u, v) = 2 \operatorname{Im}(A) + 2vB$. Setting both to be 0 gives $u = -\frac{\operatorname{Re}(A)}{B}$ and $v = -\frac{\operatorname{Im}(A)}{B}$. These values of u and v give $\lambda = -A/B$. Thus

$$F(u, v) = \sum_{j=1}^n |a_j|^2 - \frac{2|A|^2}{B} + \frac{|A|^2}{B}$$

and so

$$|A|^2 \leq \sum_{j=1}^n |a_j|^2 \sum_{j=1}^n |b_j|^2. \quad \square$$

Chapter II

Metric Spaces

II.1 Definitions & examples

Definition II.1.1. A *metric space* is a pair (X, d) consisting of a set X and a “distance function” $d: X \times X \rightarrow [0, \infty)$ such that

(M1) $d(x, y) = 0$ iff $x = y$,

(M2) $d(x, y) = d(y, x)$,

(M3) $d(x, z) \leq d(x, y) + d(y, z)$ (triangle inequality).

Examples.

- $X = \mathbb{R}$, $d(x, y) = |x - y|$.
- (Real Euclidean space) $X = \mathbb{R}^n$. The inner product $\langle x, y \rangle = \sum_{j=1}^n x_j y_j$ gives the *Euclidean* distance $d(x, y) = \sqrt{\langle x - y, x - y \rangle}$.
- (Discrete metric) Let X be any set. Then $[x \neq y]$ is a distance function on X .
- $X = \mathbb{R}^n$, $p \in [1, \infty]$. For $p \neq \infty$,

$$d_p(x, y) = \left(\sum_{j=1}^n |x_j - y_j|^p \right)^{1/p}$$

and

$$d_\infty(x, y) = \max_{1 \leq j \leq n} |x_j - y_j|.$$

If $p \neq 2$, then d_p is not induced by an inner product.

- For any metric space (X, d) and a subset $Y \subseteq X$, the restriction of d to $Y \times Y$ is a distance on Y .

Proposition II.1.2. *Given $a, b \in \mathbb{R}^n$,*

$$|\|a\| - \|b\|| \leq \|a + b\| \leq \|a\| + \|b\|.$$

Proof. From Cauchy-Schwarz,

$$\begin{aligned} \|a + b\|^2 &= \langle a + b, a + b \rangle \\ &= \|a\|^2 + 2\langle a, b \rangle + \|b\|^2 \\ &\leq \|a\|^2 + 2\|a\|\|b\| + \|b\|^2 \\ &= (\|a\| + \|b\|)^2. \end{aligned}$$

□

II.2 Metric Topology

Lecture 8.

Thursday

January 18

Definition II.2.1. Let (X, d) be a metric space.

- (i) The *open ball* centered at p or radius $\varepsilon > 0$ is the set

$$B_d(p; \varepsilon) := \{x \in X : d(p, x) < \varepsilon\}$$

This set is also called the ε -neighborhood of p . Similarly, the *closed ball* centered at p or radius $\varepsilon > 0$ is the set

$$\{x \in X : d(p, x) \leq \varepsilon\}$$

- (ii) Given a set $E \subseteq X$ and $p \in X$, p is an *interior point* of E if there exists some $\varepsilon > 0$ such that the ε -neighborhood $B(p; \varepsilon)$ is contained in E . The collection of all interior points of E , denoted E° , is called the *interior* of E .
- (iii) A set $E \subseteq X$ is said to be *open* if it is equal to its interior.
- (iv) The collection of all open sets of (X, d) is called the d -topology on X .

Remark. The empty set is always open.

Examples.

- The open ball on \mathbb{R} is an interval $(p - \varepsilon, p + \varepsilon)$.
-
- For the discrete metric,

$$B_d(p; \varepsilon) = \begin{cases} \{p\} & \varepsilon < 1 \\ X & \varepsilon \geq 1 \end{cases}$$

Every set is open, by taking any $\varepsilon = 1$.

Proposition II.2.2. *Every open ball is an open set.*

Proof. Let (X, d) be the metric. Let $p \in X$, $\varepsilon > 0$, and $q \in B(p; \varepsilon)$. Choose $\delta = \varepsilon - d(p, q) > 0$ works. We show that $B(q; \delta) \subseteq B(p; \varepsilon)$. Let $r \in B(q; \delta)$. Then from the triangle inequality,

$$\begin{aligned} d(p, r) &\leq d(p, q) + d(q, r) \\ &< d(p, q) + \delta \\ &= \varepsilon \end{aligned}$$

□

Proposition II.2.3. *The union of any collection of open sets is open, and the intersection of any finite collection of open sets is open.*

Proof. Let \mathcal{U} be a collection of open sets. Let $E = \bigcup_{U \in \mathcal{U}} U$. For any $p \in E$, p is contained in some $U \in \mathcal{U}$. Then there exists some $\varepsilon > 0$ such that $B(p; \varepsilon) \subseteq U \subseteq E$.

Let U_1, \dots, U_n be open sets and let $E = \bigcap_{i=1}^n U_i$. For any $p \in E$, $p \in U_i$ for all i . Then there exist $\varepsilon_1, \dots, \varepsilon_n > 0$ such that $B(p; \varepsilon_i) \subseteq U_i$ for all i . Letting ε be the minimum of the ε_i 's, we have $B(p; \varepsilon) \subseteq U_i$ for all i . So $B(p; \varepsilon) \subseteq E$. \square

Definition II.2.4. Let (X, d) be a metric space and $E \subseteq X$.

- (i) Given $p \in X$, we say that p is an *accumulation point* of E if for every $\varepsilon > 0$, $B(p; \varepsilon)$ contains a point $q \in E$ such that $q \neq p$.
- (ii) A point $p \in E$ is said to be *isolated* in E if it is not an accumulation point of E .
- (iii) E is said to be *closed* if it contains all its accumulation points.
- (iv) The *closure* of E , denoted \bar{E} , is the union of E with all its accumulation points.
- (v) The boundary of E is the set $\partial E = \bar{E} \setminus E^\circ$.

Examples.

- In the discrete metric, every point is isolated in every subset.
- Finite subsets have no accumulation points.

Remarks.

- p need not lie in E to be an accumulation point.
- If p is an accumulation point of E , then every neighborhood of p contains infinitely many points of E .

Examples.

- Closed intervals are closed sets.
- $E = [0, 1)$ is neither open nor closed. $\bar{E} = [0, 1]$, $E^\circ = (0, 1)$ and $\partial E = \{0, 1\}$.
- Finite sets are always closed.
- In the discrete metric, every set is both open and closed.

Proposition II.2.5. *A set is closed iff its complement is open.*

Proof. Let $E \subseteq X$ be closed. Let $x \in E^c$. Since x is not a limit point of E , there exists an open ball around it that contains no points of E . Thus x is an interior point of E^c . This gives that E^c is open.

Now let $E \subseteq X$ be open. Let x be a limit point of E^c . Then there is no open ball around x that lies entirely in E . Thus x cannot lie in E . This gives that E^c is closed. \square

Corollary II.2.6. *The intersection of any collection of closed sets is closed, and the union of any finite collection of closed sets is closed.*

Proof. Propositions II.2.3 and II.2.5 and De Morgan's laws. \square

Theorem II.2.7.

- (i) *The closure of a set is closed.*
- (ii) *If $A \subseteq B$, then $\bar{A} \subseteq \bar{B}$.*
- (iii) *\bar{E} is the smallest closed set containing E . That is,*

$$\bar{E} = \bigcap_{\substack{F \supseteq E \\ F \text{ closed}}} F.$$

Proof.

- (i) Let x be a limit point of \bar{E} . We will show that x is a limit point of E . Let $\varepsilon > 0$. If $B(x; \varepsilon)$ contains no point from E , it must contain a limit point of E . But then there are points of E arbitrarily close to it, within the ball. Thus $B(x; \varepsilon)$ contains points of E for any $\varepsilon > 0$ and so x is a limit point of E .

- (ii) Every point in A is a point in B . Every limit point of A is a limit point of B .
- (iii) Every closed set F containing E must contain
 - every point of E , and
 - every limit point of E .

Thus $\bar{E} \subseteq F$ for every such F . so \bar{E} is the smallest closed set containing E . \square

Definition II.2.8 (Relative topology). Given a metric space (X, d) and subsets $E \subseteq Y$, we say that E is open (resp. closed) *relative to* Y if E is an open (resp. closed) set in the metric space $(Y, d|_Y)$.

Proposition II.2.9. Let (X, d) be metric space and $E \subseteq Y \subseteq X$. Then E is open relative to Y iff there exists an open set $F \subseteq X$ such that $E = F \cap Y$.

Proof. Let E be open relative to Y . For each $x \in E$, there exists an $\varepsilon_x > 0$ such that $B_Y(x, \varepsilon_x) \subseteq E$. Let $F = \bigcup_{x \in E} B_X(x, \varepsilon_x)$. Then F is open relative to X and $F \cap Y = E$.

Let $E = F \cap Y$ where F is open in X . For every $x \in F$ there exists an $\varepsilon > 0$ such that $B_X(x, \varepsilon) \subseteq F$. Then for any $y \in E$, $B_Y(y, \varepsilon) = B_X(y, \varepsilon) \cap Y$ is contained in $F \cap Y = E$. So E is open in Y . \square

Corollary II.2.10. Let (X, d) be metric space and $E \subseteq Y \subseteq X$. Then E is closed relative to Y iff there exists a closed set $F \subseteq X$ such that $E = F \cap Y$.

Proof. Propositions II.2.5 and II.2.9. \square

II.3 Compactness

Definition II.3.1. A subset $E \subseteq (X, d)$ is said to be *bounded* if there exists a $p \in X$ and $M > 0$ such that $E \subseteq B(p; M)$.

Equivalently, E is bounded if for all $x \in X$, there exists an $M > 0$ such that $E \subseteq B(x; M)$. Or, E is bounded if there exists an $M > 0$ such that $d(x, y) < M$ for all $x, y \in E$.

Lecture 10.

Wednesday

January 24

Consider $E = \{p \in \mathbb{Q} : 2 < p^2 < 3\}$. Then E is both closed and bounded in $(\mathbb{Q}, |\cdot|)$. However, continuous functions on E are neither uniformly continuous nor bounded.

Definition II.3.2 (Open cover). Let $E \subseteq (X, d)$. An open cover $\{\mathcal{U}_\alpha\}_{\alpha \in \Lambda}$ of E in X is a collection of open sets \mathcal{U}_α such that $E \subseteq \bigcup_{\alpha \in \Lambda} \mathcal{U}_\alpha$.

Definition II.3.3 (Compact set). A subset $E \subseteq (X, d)$ is said to be compact if any open cover $\mathcal{U} = \{\mathcal{U}_\alpha\}_{\alpha \in \Lambda}$ of E in X admits a finite subcover of E , i.e., there exist $\alpha_1, \dots, \alpha_k \in \Lambda$ such that $E \subseteq \bigcup_{i=1}^k \mathcal{U}_{\alpha_i}$.

Examples.

- $E \subseteq (X, d)$ is finite. Let \mathcal{U} be an open cover of $E = \{p_1, \dots, p_n\}$. Then for each $p_j \in E$, there exists $\alpha_j \in \Lambda$ such that $p_j \in \mathcal{U}_{\alpha_j}$. Then $E \subseteq \bigcup_{j=1}^n \mathcal{U}_{\alpha_j}$.
- $E = (0, 1)$ is not compact in $(\mathbb{R}, |\cdot|)$.

Proof. Let $\mathcal{U}_n = (\frac{1}{n+2}, \frac{1}{n})$ for $n \in \mathbb{N}^*$. Then $\mathcal{U} = \{\mathcal{U}_n\}_{n \in \mathbb{N}^*}$ is an open cover of E . However, \mathcal{U} does not admit a finite subcover of E . For any finite $\{\mathcal{U}_{n_1}, \dots, \mathcal{U}_{n_k}\}$, let $n_0 = \max\{n_j : 1 \leq j \leq k\}$. Then $\bigcup \mathcal{U}_{n_j} \subseteq (\frac{1}{n_0+2}, 1)$ and thus is not a cover of E . \square

- $E = [0, 1]$ is compact in $(\mathbb{R}, |\cdot|)$. In fact, all rectangles (sets of the form $[a_1, b_1] \times \dots \times [a_n, b_n]$) are compact in $(\mathbb{R}^n, \|\cdot\|)$.

Theorem II.3.4. Let $E \subseteq (\mathbb{R}^n, \|\cdot\|)$. Then the following are equivalent:

- (1) E is compact.
- (2) E is closed and bounded.
- (3) Every infinite subset of E admits a limit point in E .

Remark. The equivalence between (1) and (2) is known as the Heine-Borel theorem.

We first show that (1) \implies (2) in a general metric space. This is not necessary for the theorem, since we will later show (1) \implies (3) \implies (2) \implies (1) anyway. But (2) \implies (1) is only valid in \mathbb{R}^n , so that won't yield (1) \implies (2) in a general space.

Proof that (1) \implies (2) in general. Let $E \subseteq (X, d)$ be compact. Let $z \in E^c$. For any $y \in E$, let $\delta_y = d(y, z)/2$. Note that $B(z, \delta_y) \cap B(y, \delta_y) = \emptyset$.

Then $\mathcal{U} = \{B(y; \delta_y) : y \in E\}$ is an open cover of E . Since E is compact, \mathcal{U} admits a finite subcover of E . That is, there exist $y_1, \dots, y_k \in E$ such that $E \subseteq \bigcup_{i=1}^k B(y_i; \delta_{y_i})$. Let $\delta = \min\{\delta_{y_i}\}$. Then $B(z; \delta) \cap E = \emptyset$, so $B(z; \delta) \subseteq E^c$. This shows that E^c is open, so E is closed.

For boundedness, take the largest ball from finite subcover of E in $\bigcup_{R>0} B(p; R)$ for some $p \in E$. \square

To show that (2) \implies (1) in $(\mathbb{R}^n, \|\cdot\|)$, we first show that for any $R \in \mathbb{R}$, the set $[-R, R]^n$ is compact.

Theorem II.3.5. *All rectangles of the form $[-R, R]^n$ are compact in $(\mathbb{R}^n, \|\cdot\|)$.*

Proof. Fix an $R > 0$. Let $I_0 = [-R, R]^n$. Note that

$$\text{diam}(I_0) = \max\{\|x - y\| \mid x, y \in I_0\} = 2R\sqrt{n}.$$

Let \mathcal{U} be an open cover of I_0 . Suppose this has no finite subcover of I_0 . We partition I_0 into 2^n equal rectangles of the form $J_1 \times J_2 \times \dots \times J_n$, where each J_i is either $[-R, 0]$ or $[0, R]$. The diameter of each of these rectangles is $R\sqrt{n}$. By the pigeonhole principle, there exists I_1 among these rectangles that does not admit a finite subcover in \mathcal{U} .

We continue this process to obtain a sequence of rectangles $I_0 \supseteq I_1 \supseteq I_2 \supseteq \dots$, none of which admit a finite subcover in \mathcal{U} , with $\text{diam}(I_k) = \frac{2R}{2^k} \sqrt{n}$.

We use the nested interval property (lemma II.3.6) to obtain a point $x \in \bigcap_{k=1}^{\infty} I_k$. Since \mathcal{U} covers I_0 , there exists $U \in \mathcal{U}$ that contains x . Since U is open, it contains some ε -ball around x . But the diameters of the I_k s decrease to 0, so $I_k \subseteq U$ for some k . This contradicts that I_k does not admit a finite subcover in \mathcal{U} .

Thus the original rectangle I_0 admits a finite subcover in \mathcal{U} . \square

Lemma II.3.6 (Nested interval theorem). *Let $I_0 \supseteq I_1 \supseteq \dots$ be a sequence of closed rectangles in \mathbb{R}^n . Then $\bigcap_{k=1}^{\infty} I_k \neq \emptyset$.*

Proof. Let each $I_k = [a_{1k}, b_{1k}] \times \cdots \times [a_{nk}, b_{nk}]$. Then $(a_{ik})_{k \in \mathbb{N}}$ and $(b_{ik})_{k \in \mathbb{N}}$ are bounded sequences in \mathbb{R} . Let $A_i = \sup\{a_{ik} \mid k \in \mathbb{N}\}$. Note that each b_{ik} is an upper bound for the set $\{a_{ik} \mid k \in \mathbb{N}\}$, so $A_i \leq b_{ik}$ for all k .

Let $A = (A_1, \dots, A_n)$. For each k , $A \in I_k$ since $A_i \in [a_{ik}, b_{ik}]$ for all i . Thus $\bigcap_{k=1}^{\infty} I_k \ni A$. \square

How do we go from the compactness of rectangles to the compactness of arbitrary closed and bounded sets in \mathbb{R}^n ? We need the following theorem.

Lecture 11.

Thursday

January 25

Theorem II.3.7. *A closed subset of a compact set is compact.*

Proof. Let $E \subseteq X$ be compact and $F \subseteq E$ be closed. Let \mathcal{U} be an open cover of F . Then $\mathcal{U} \cup \{F^c\}$ is an open cover of E . This contains a finite subcover \mathcal{V} . Then $\mathcal{V} \setminus \{F^c\} \subseteq \mathcal{U}$ is a finite subcover of F . \square

We are now ready to show that closed and bounded sets in \mathbb{R}^n are compact.

Proof that (2) \implies (1) in \mathbb{R}^n . Let $E \subseteq \mathbb{R}^n$ be closed and bounded. There is an $R > 0$ such that $E \subseteq B(0; R)$, but $B(0; R) \subseteq [-R, R]^n$. So E is a closed subset of the compact set $[-R, R]^n$. By theorem II.3.7, E is compact. \square

Theorem II.3.8. *Let $\{K_\alpha\}_{\alpha \in \Lambda}$ be a collection of compact sets in (X, d) such that any non-empty finite subcollection has non-empty intersection. Then $\bigcap_{\alpha \in \Lambda} K_\alpha \neq \emptyset$.*

Proof. Suppose $\bigcap_{\alpha \in \Lambda} K_\alpha = \emptyset$. Choose a $K \in \{K_\alpha\}_{\alpha \in \Lambda}$. No element in K is in every other K_α . Let $U_\alpha = K_\alpha^c$ for each α . Any point in K is in at least one U_α . Then $\{U_\alpha\}_{\alpha \in \Lambda}$ is an open cover of K . Since K is compact, there is a finite subcover $U_{\alpha_1}, \dots, U_{\alpha_n}$. But then

$$\begin{aligned} K &\subseteq U_{\alpha_1} \cup \cdots \cup U_{\alpha_n} \\ &= K_{\alpha_1}^c \cup \cdots \cup K_{\alpha_n}^c \\ &= (K_{\alpha_1} \cap \cdots \cap K_{\alpha_n})^c \end{aligned}$$

so $K \cap K_{\alpha_1} \cap \cdots \cap K_{\alpha_n} = \emptyset$, a contradiction. \square

Corollary II.3.9. *Let $K_0 \supseteq K_1 \supseteq K_2 \supseteq \dots$ be non-empty compact sets in (X, d) . Then $\bigcap_{n \in \mathbb{N}} K_n \neq \emptyset$.*

Remark. This cannot be used to prove the nested interval property, since the proof of compactness of rectangles in \mathbb{R}^n itself relies on the nested interval property.

Theorem II.3.10. *Every infinite subset of a compact set has a limit point in the set.*

Proof. Let $E \subseteq (X, d)$ be compact and $F \subseteq E$ be infinite. Suppose F has no limit point in E . Then for every $z \in E$, there exists an $\varepsilon_z > 0$ such that $B(z; \varepsilon_z)$ contains no point of F , except possibly z . Then $\{B(z; \varepsilon_z)\}_{z \in E}$ is an open cover of E .

Since E is compact, this contains a finite subcover. But each $B(z; \varepsilon_z)$ contains at most one point of F , so only finitely many points of F are covered. Contradiction. \square

Proof that (3) \implies (2). Suppose (3) holds on some $E \subseteq (\mathbb{R}^n, \|\cdot\|)$ but E is not bounded. Let $x_0 \in E$. We can produce a sequence $(x_n)_{n \in \mathbb{N}} \subseteq E$ such that

$$\|x_{n+1}\| > \|x_n\| + 1 \text{ for all } n \in \mathbb{N}.$$

This cannot have a limit point in E (or anywhere) since for any $x \in E$, $B(x, 1)$ contains at most one point of the sequence.

Now suppose (3) holds on E but E is not closed. Then there exists a $z \in E^c$ such that z is a limit point of E . Then there exists a sequence $(x_n)_{n \in \mathbb{N}} \subseteq E$ such that $\|x_j - z\| < \frac{1}{j}$ for all $j \in \mathbb{N}$. The set $F = \{x_n\}_{n \in \mathbb{N}}$ is infinite (otherwise, the minimum distance is the infimum, which is zero, but $z \notin E$). Then F must have a limit point in E .

For any $y \in \mathbb{R}^n$,

$$\begin{aligned} \|x_j - y\| &\geq \|z - y\| - \|x_j - z\| \\ &\geq \|z - y\| - \frac{1}{j}. \end{aligned}$$

If $\|z - y\|$ is positive, then there are only finitely many x_j within a distance $\|z - y\|$ of y . Hence y can be a limit point of F only if $y = z$. \square

Theorem II.3.11. *Let $E \subseteq Y \subseteq (X, d)$ where Y is compact in X . Then E is compact relative to Y if and only if it is compact in X .*

Proof. We use proposition II.2.9.

Suppose E is compact in Y . Let \mathcal{U} be an open cover of E in X . Then $\mathcal{V} = \{U \cap Y\}_{U \in \mathcal{U}}$ is an open cover of E in Y . This has a finite subcover $\{U_1 \cap Y, \dots, U_n \cap Y\}$. Then $\{U_1, \dots, U_n\}$ is a finite subcover of E in \mathcal{U} .

Suppose E is compact in X . Let \mathcal{V} be an open cover of E in Y . Then for each $V \in \mathcal{V}$, there exists a set U_V open in X such that $V = U_V \cap Y$, so

that $\mathcal{U} = \{U_V\}_{V \in \mathcal{V}}$ is an open cover of E in X . This has a finite subcover $\{U_{V_1}, \dots, U_{V_n}\}$. Then $\{V_1, \dots, V_n\}$ is a finite subcover of E in \mathcal{V} . \square

II.4 Connected Sets

Lecture 12.

Monday

January 29

Definition II.4.1.

- (a) Let (X, d) be a metric space. A pair of sets $A, B \subseteq X$ are said to be *separated* in X if $\bar{A} \cap B = A \cap \bar{B} = \emptyset$.
- (b) A set $E \subseteq X$ is said to be *disconnected* if it is the union of two separated sets in X .
- (c) E is *connected* if it is not disconnected.

Examples.

- Sets $A = (-1, 0)$ and $B = (0, 1)$ are separated in \mathbb{R} . Note that sgn is continuous on $A \cup B$ but does not satisfy the intermediate value property.
However, if $A = (-1, 0]$ instead, then all continuous functions on $A \cup B$ satisfy the intermediate value property.
- The empty set is connected.
- \mathbb{Q} is disconnected in \mathbb{R} . The partition $\{\mathbb{Q} \cap (-\infty, \sqrt{2}), \mathbb{Q} \cap (\sqrt{2}, \infty)\}$ separates \mathbb{Q} .
- \mathbb{Q} is disconnected even in \mathbb{Q} .

Exercise II.4.2. Let $E \subseteq Y \subseteq (X, d)$. Then E is connected relative to Y iff E is connected in X .

Theorem II.4.3. Let $E \subseteq \mathbb{R}$. Then E is connected iff E is convex, i.e., for all $x < y \in E$, $[x, y] \subseteq E$.

Proof. Suppose E is connected, but not convex, i.e., there exist $x < y \in E$ and some $r \in (x, y)$ that is not in E . Then $A = (-\infty, r] \cap E$ and $B = [r, \infty) \cap E$ separate E .

Conversely, suppose E is convex but not connected. Then there exist $A, B \subseteq E$ that separate E . Let $x \in A$ and $y \in B$ and suppose WLOG that $x < y$. Note that $A \cap [x, y]$ is non-empty and bounded. Let $r = \sup(A \cap [x, y])$.

By the lemma below, $r \in A \cap [x, y] \subseteq \bar{A} \cap [x, y]$ so $r \in \bar{A}$. Disconnectedness forces that $r \notin B \iff r \in A$ so $x \leq r < y$.

But since r is the supremum of $A \cap [x, y]$, $(r, y) \subseteq B$. This gives $r \in \bar{B}$, violating the separation of A and B . \square

II.5 The Cantor Set

Definition II.5.1 (Perfect set). A set $E \subseteq (X, d)$ is said to be *perfect* if every point of E is a limit point of E .

Note that $E = [0, 1]$ is perfect in \mathbb{R} . Can we produce a “sparse” perfect set? Throwing away isolated points makes the set open. Throwing away a finite number of open sets preserves perfectness, but there are still *intervals of positive length*.

Can we produce a perfect set such that

- (i) it contains no intervals of positive length?
- (ii) E is *nowhere dense*, i.e., $(\bar{E})^\circ = \emptyset$?

Note that the second condition implies the first.

Definition II.5.2 (Ternary expansion). Let $x \in [0, 1]$. A *ternary expansion* of x is a sequence $(d_1, d_2, \dots) \subseteq \{0, 1, 2\}$ such that

$$x = \sup \left\{ D_k = \sum_{j=1}^{k-1} \frac{d_j}{3^j} : k \geq 1 \right\}$$

which is equivalent to

$$\sum_{j=1}^{\infty} \frac{d_j}{3^j} = x$$

We write $x = 0.d_1d_2d_3\dots$ to denote this.

Example. For $x = \frac{1}{3}$, we have both $x = 0.1000\dots$ and $x = 0.0222\dots$, so ternary expansions are not unique.

Lecture 13.
Wednesday
January 31

	0	1	$\frac{1}{3}$	$\frac{2}{3}$	$\frac{4}{9}$	$\frac{1}{2}$
A	0.000...		0.100...	0.200...	0.1100...	0.111...

Table II.1: Scheme A vs Scheme B

Let $I_0 = [0, \frac{1}{3}]$, $I_1 = [\frac{1}{3}, \frac{2}{3}]$ and $I_2 = [\frac{2}{3}, 1]$. Let $x \in [0, 1]$. Choose $d_1 = j$ such that $x \in I_j$ (in ambiguous cases, pick any one). Then

$$\begin{aligned}
 x &\in \left[\frac{d_1}{3}, \frac{d_1 + 1}{3} \right] \\
 \implies 0 &\leq x - \frac{d_1}{3} \leq \frac{1}{3} \\
 \implies D_1 &\leq x \leq D_1 + \frac{1}{3}
 \end{aligned}$$

Let I_{j0}, I_{j1}, I_{j2} be the subdivisions of I_j . Choose $d_2 = l$, where $x \in I_{jl}$ iff

$$\begin{aligned}
 x &\in \left[\frac{d_1}{3} + \frac{d_2}{9}, \frac{d_1}{3} + \frac{d_2 + 1}{9} \right] \\
 \implies D_2 &\leq x \leq D_2 + \frac{1}{9}
 \end{aligned}$$

How do we break ties?

Scheme A If at the k^{th} state, $x \in [0, 1]$ is an endpoint of 2 intervals, pick the right interval. This gives a unique expansion. That is, pick d_k such that $D_k \leq x < D_k + \frac{1}{3}$.

Scheme B For $x \in (0, 1]$, always pick the left interval. That is, pick d_k such that $D_k < x \leq D_k + \frac{1}{3}$.

We make the following observations:

- Ambiguity only occurs at endpoints of “middle thirds”.
- Say x is an endpoint of a middle third. Let k be the first stage where ambiguity occurs. Then if x is the left endpoint, scheme A gives $x = 0.d_1d_2 \dots d_{k-1}1000\dots$ and scheme B gives $x = 0.d_1d_2 \dots d_{k-1}0222\dots$. If x is the right endpoint, scheme A gives $x = 0.d_1d_2 \dots d_{k-1}2000\dots$ and scheme B gives $x = 0.d_1d_2 \dots d_{k-1}1222\dots$.

Note that this ambiguity can be resolved by a scheme C, which picks the expansion which has no 1 starting from the point of ambiguity.

Theorem II.5.3. *There exists a non-empty $E \subseteq [0, 1]$ such that*

- (i) E is compact.
- (ii) $E = \{\text{limit points of } E\}$.
- (iii) $E^\circ = \overline{E}^\circ = \emptyset$.
- (iv) E is uncountable.

Proof.

$$E = \{x \in [0, 1] : x \text{ admits at least one ternary expansion with only 0's and 2's}\}$$

We can construct this set by removing the middle thirds.

$$\begin{aligned} E_0 &= [0, 1] \\ E_1 &= E_0 \setminus \left(\frac{1}{3}, \frac{2}{3}\right) \\ &= \left[0, \frac{1}{3}\right] \cup \left[\frac{2}{3}, 1\right] \\ E_2 &= E_1 \setminus \left[\left(\frac{1}{9}, \frac{2}{9}\right) \cup \left(\frac{4}{9}, \frac{5}{9}\right) \cup \left(\frac{7}{9}, \frac{8}{9}\right)\right] \\ E_m &= E_{m-1} \setminus \bigcup_{k=0}^{3^{m-1}-1} \left(\frac{3k+1}{3^m}, \frac{3k+2}{3^m}\right) \end{aligned}$$

We claim that $E = \bigcap_{m=1}^{\infty} E_m$ satisfies the conditions of the theorem. First note that $E_1 \subseteq E_2 \subseteq \dots$, so for any $m_1 < m_2 < \dots < m_k$, $\bigcap_{i=1}^k E_{m_i} = E_{m_k}$ is non-empty. By theorem II.3.8, E is non-empty.

Since E is the intersection of closed sets, E is closed. Since E is bounded, E is compact.

We have that $E^\circ = \emptyset$ since E does not contain any open intervals. Formally, we will show that for any interval (a, b) , there exist k and m such that $\left(\frac{3k+1}{3^m}, \frac{3k+2}{3^m}\right)$ is contained in (a, b) .

Heuristically, we see that the length of the removed intervals is $\frac{1}{3} + \frac{1}{9} + \cdots = 1$, so that the remaining set cannot contain any interval of positive length.

Uncountability is by a diagonal argument. \square

Chapter III

Sequences & Series

Lecture 14.
Thursday
February 01

III.1 Sequences & Subsequences

Definition III.1.1. Let (X, d) be a metric space. A sequence in X is a function $f: \mathbb{N} \rightarrow X$, more commonly written as $(f(k))_{k \in \mathbb{N}} \subseteq X$.

We say that a sequence $(x_n)_{n \in \mathbb{N}}$ *converges* in X if there exists an $x \in X$ such that for every $\varepsilon > 0$ there exists an $N \in \mathbb{N}$ such that for all $n \geq N$, $d(x_n, x) < \varepsilon$. In this case, we call x a limit of $(x_n)_{n \in \mathbb{N}}$ and write

$$\lim_{k \rightarrow \infty} x_k = x \quad \text{or} \quad x_k \rightarrow x \text{ as } k \rightarrow \infty.$$

If $(x_n)_{n \in \mathbb{N}}$ does not converge, we say that it *diverges*.

Examples.

- When $(X, d) = (\mathbb{R}, |\cdot|)$, this definition reduces to the definition in UMA101.
- Let $x_n = (\frac{1}{n}, \frac{2}{n^2}) \in (\mathbb{R}^2, \|\cdot\|)$ for each $n \geq 1$.
We claim that $\lim_{n \rightarrow \infty} x_n = (0, 0)$.

Proof. Let $\varepsilon > 0$. Choose an $N > \frac{\sqrt{5}}{\varepsilon}$. Then for all $n \geq N$,

$$\begin{aligned} \left\| \left(\frac{1}{n}, \frac{2}{n^2} \right) \right\|^2 &= \frac{1}{n^2} + \frac{4}{n^4} \\ &\leq \frac{5}{n^2} \\ &< \varepsilon. \end{aligned}$$

□

- Let $x = (\frac{1}{n}, (-1)^n)_{n \in \mathbb{N}^*}$ with standard norm. Then $(x_n)_{n \in \mathbb{N}^*}$ diverges.

Theorem III.1.2. Let (X, d) be a metric space.

- (i) Let $(x_n)_{n \in \mathbb{N}} \subseteq X$. Then, $\lim_{n \rightarrow \infty} x_n = x$ iff every ε -ball centred at x contains all but finitely many terms of (x_n) .
- (ii) Suppose $\lim_{n \rightarrow \infty} x_n = x$ and $\lim_{n \rightarrow \infty} x_n = y$. Then $x = y$.
- (iii) If $(x_n)_{n \in \mathbb{N}} \subseteq X$ converges, then $\{x_n : n \in \mathbb{N}\}$ is a bounded set in (X, d) .
- (iv) Let $E \subseteq X$. Then $x \in \bar{E}$ iff there exists a sequence $(x_n) \subseteq E$ such that $\lim_{n \rightarrow \infty} x_n = x$.

Proof.

- (i) Let (x_n) be convergent to x . Then all terms except the first N lie inside the ε -neighborhood of x . The converse is similarly true.
- (ii) Let x and y be distinct limits of (x_n) . Choose $\varepsilon = \frac{d(x,y)}{2} > 0$. Then for large enough n ,

$$\begin{aligned} d(x, y) &\leq d(x, x_n) + d(x_n, y) \\ &< \varepsilon + \varepsilon \\ &= d(x, y). \end{aligned} \quad \square$$

- (iii) Let (x_n) be convergent to x . Let N be such that for all $n \geq N$, $d(x_n, x) < 1$. Then $\rho = \sum_{k=0}^N d(x_k, x) + 1$ works as a radius for $B(x, \rho) \supseteq \{x_n : n \in \mathbb{N}\}$.
- (iv) Let $x \in \bar{E}$. Then every ε -neighborhood of x intersects E . By the axiom of choice, we can choose a sequence $(x_n) \subseteq E$ such that $d(x_n, x) < \frac{1}{n}$. This converges to x .

Conversely if there exists a sequence $(x_n) \rightarrow x$ within E , then every ε -neighborhood of x intersects E .

Definition III.1.3. Let $(x_n)_{n \in \mathbb{N}} \subseteq X$. Let $(n_k)_{k \in \mathbb{N}}$ be a strictly increasing sequence in \mathbb{N} . Then $(x_{n_k})_{k \in \mathbb{N}}$ is called a *subsequence* of (x_n) .

Any limit of a subsequence of (x_n) is called a *subsequential limit* of (x_n) .

Example. Let $x_n = (\frac{1}{n}, (-1)^n) \subseteq \mathbb{R}^2$ for $n \geq 1$. Then (x_n) is not convergent, but has subsequential limits $(0, 1)$ and $(0, -1)$ corresponding to the subsequences (x_{2n}) and (x_{2n-1}) respectively.

Lecture 15.
Monday
February 05

Theorem III.1.4. Let $(x_n)_{n \in \mathbb{N}} \subseteq (X, d)$. Then $\lim_{n \rightarrow \infty} x_n = x$ iff every subsequence converges to x .

Proof. Suppose (x_n) is convergent. Let $(y_k) = (x_{n_k})$ be a subsequence. Then for any $\varepsilon > 0$, there exists $N \in \mathbb{N}$ such that $d(x_n, x) < \varepsilon$ for all $n \geq N$. But this same N works for the subsequence, since $n_k \geq k$. Thus each subsequence converges to x .

Now suppose every subsequence converges to x . Since the sequence itself is a subsequence, it converges to x . \square

Theorem III.1.5. Let $E \subseteq (X, d)$. Then the following are equivalent.

- (1) E is compact.
- (2) Every infinite subset of E has a limit point in E .
- (3) Every sequence in E has a subsequential limit in E .

(1) \iff (2) is by theorem II.3.4. We prove (2) \iff (3).

Proof of (2) \Rightarrow (3). Suppose every infinite subset of E has a limit point in E . Let $(x_n)_{n \in \mathbb{N}}$ be a sequence in E , and let S be the set of all x_n .

If S is finite, then by the Pigeonhole Principle, there exists some $x \in S$ such that $x_n = x$ for infinitely many n . Then the constant sequence (x) is a subsequence of (x_n) , whose limit x is in E .

If not, then S is infinite, so it has a limit point $p \in E$. Thus for every $k \in \mathbb{N}$, there exists an $N_k \in \mathbb{N}$ such that $x_{N_k} \neq p \in B(p; \frac{1}{k})$.

Let n_1 be such that $d(x_{n_1}, p) < 1$. For n_{k+1} , consider $S \setminus \{x_0, \dots, x_{n_k}\}$. p is also a limit point of this set (why?), so there exists an $n_{k+1} > n_k$ such that $d(x_{n_{k+1}}, p) < \frac{1}{k+1}$. Then $(x_{n_k})_k$ is a subsequence of $(x_n)_n$, and $\lim_{k \rightarrow \infty} x_{n_k} = p \in E$. \square

Corollary III.1.6. Let $(x_n)_{n \in \mathbb{N}} \subseteq (\mathbb{R}^k, \|\cdot\|)$ be a bounded sequence. Then (x_n) has a convergent subsequence.

Proof. Let $p \in \mathbb{R}^k$ and $R > 0$ be such that $(x_n) \subseteq B(p; R) \subseteq \overline{B(p; R)}$ which is compact (why?). Then by the previous theorem, (x_n) has a convergent subsequence. \square

Lecture 16.

Wednesday

February 07

Proof of (3) \Rightarrow (2). Let $S \subseteq E$ be an infinite set. Thus there exists a sequence $(x_n)_n \subseteq S$ of distinct elements.

By (3), there exists a subsequence $(x_{n_k})_k$ of $(x_n)_n$ such that $(x_{n_k})_k$ is convergent to some $x \in E$. By the sequential characterization of closures, $x \in \bar{S}$.

Thus for all $\varepsilon > 0$, there exists a $k_\varepsilon \in \mathbb{N}$ such that for all $k \geq k_\varepsilon$, we have that $d(x_{n_k}, x) < \varepsilon$. Thus x is a limit point of S in E . \square

III.2 Cauchy Sequences & Completeness

Recall the HW2 problem to show that the sequence $(x_n)_n$ given by

$$x_n = \begin{cases} 2 & \text{if } n = 0 \\ x_{n-1} - \frac{x_{n-1}^2 - 2}{2x_{n-1}} & \text{if } n \geq 1 \end{cases}$$

is \mathbb{Q} -Cauchy but not convergent in \mathbb{Q} . This is an application of the Newton-Raphson method.

III.2.1 Newton-Raphson Method (Informal)

Given a function $f: \mathbb{R} \rightarrow \mathbb{R}$, we want to find a root of f . We pick some initial guess $x_0 \in \mathbb{R}$, and iterate via

$$x_n = x_{n-1} - \frac{f(x_{n-1})}{f'(x_{n-1})}.$$

Under *some* assumptions on f and x_0 , $(x_n)_n$ is Cauchy. Then

$$f(x_{n-1}) = f'(x_{n-1})(x_{n-1} - x_n) \rightarrow 0$$

If $\lim_{n \rightarrow \infty} x_n = l$, and f is continuous, then

$$f(l) = \lim_{n \rightarrow \infty} f(x_n) = 0.$$

Definition III.2.1 (Cauchy sequence). Let $(x_n)_{n \in \mathbb{N}} \subseteq (X, d)$. We say that (x_n) is a *Cauchy sequence* if for every $\varepsilon > 0$, there exists an $N \in \mathbb{N}$ such that whenever $n, m \geq N$, $d(x_n, x_m) < \varepsilon$.

Definition III.2.2 (Completeness). (X, d) is said to be a *complete* metric space if every Cauchy sequence in (X, d) is convergent.

Theorem III.2.3.

(a) Every convergent sequence is Cauchy.

(b) Every Cauchy sequence is bounded.

Proof. Trivial. □

Theorem III.2.4. Every compact metric space is complete.

Proof. Let (X, d) be compact and let $(x_n)_n$ be a Cauchy sequence in X . Since X is compact, $(x_n)_n$ has a convergent subsequence $(x_{n_k})_k$ converging to some $x \in X$ (by theorem III.1.5).

Then $(x_n)_n$ also converges to x by the triangle inequality. For large enough n , $d(x_n, x) \leq d(x_n, x_{n_n}) + d(x_{n_n}, x) < 2\varepsilon$. □

Theorem III.2.5. $(\mathbb{R}^d, \|\cdot\|)$ is complete.

Proof. Let $(x_n)_n$ be a Cauchy sequence in \mathbb{R}^d . Then it must be bounded. Take a closed ball B centered at x_0 containing all elements of $(x_n)_n$. This is compact, and so the above theorem applies to give that $(x_n)_n$ has a limit in $B \subseteq \mathbb{R}^d$. □

Exercise III.2.6. Every increasing and bounded above sequence in \mathbb{Q} or \mathbb{R} is Cauchy.

Proof. Suppose not. Then there exists an $\varepsilon > 0$ such that for all $N \in \mathbb{N}$, there exist $n(N) > m(N) \geq N$ such that $|x_{n(N)} - x_{m(N)}| \geq \varepsilon$.

Let $m_0 = m(0)$ and $n_0 = n(0)$. For $k \geq 1$, let $m_k = m(n_{k-1})$ and $n_k = n(n_{k-1})$. Then

$$\begin{aligned} x_{n_k} &\geq x_{m_k} + \varepsilon \\ &\geq x_{n_{k-1}} + \varepsilon \end{aligned}$$

and so $(x_{n_k})_k$ is a subsequence with each term at least ε more than the last. Thus $x_{n_k} \geq x_0 + k\varepsilon$ for all $k \in \mathbb{N}$, which contradicts boundedness. □

Alternatively, we could see \mathbb{Q} as a subset of \mathbb{R} , and use the fact that a bounded monotone sequence in \mathbb{R} is convergent.

III.3 Sequences in \mathbb{R}

Definition III.3.1 (The Extended Reals). The *extended real line* is the set of real numbers along with 2 formal symbols $+\infty$ and $-\infty$, denoted by

$$\bar{\mathbb{R}} = \mathbb{R} \cup \{-\infty, +\infty\}.$$

$\bar{\mathbb{R}}$ will be endowed with the order

$$-\infty < x < \infty \text{ for all } x \in \mathbb{R},$$

along with the usual order on \mathbb{R} . We extend the algebraic operations on \mathbb{R} to $\bar{\mathbb{R}}$.

- $x + \infty = +\infty$, $x - \infty = -\infty$ for all $x \in \mathbb{R}$.
- $x \cdot (+\infty) = +\infty$, $x \cdot (-\infty) = -\infty$ for all $x \in \mathbb{R}$, $x > 0$.
- $x \cdot (+\infty) = -\infty$, $x \cdot (-\infty) = +\infty$ for all $x \in \mathbb{R}$, $x < 0$.
- $\frac{x}{+\infty} = \frac{x}{-\infty} = 0$, for all $x \in \mathbb{R}$.

If $E \subseteq \mathbb{R}$ is not bounded above in \mathbb{R} , we say $\sup E = +\infty$.

When constructing \mathbb{R} through Dedekind cuts, $\bar{\mathbb{R}}$ can be constructed by relaxing the condition that a cut must be neither empty nor the whole of \mathbb{Q} . Then \emptyset is a Dedekind cut represented as $-\infty$, and \mathbb{Q} is a Dedekind cut represented as $+\infty$.

Definition III.3.2. Let $(x_n)_{n \in \mathbb{N}} \subseteq \mathbb{R}$. Suppose that for all $M \in \mathbb{R}$, there is an $N \in \mathbb{N}$ such that for all $n \geq N$, $x_n \geq M$. Then we say that $x_n \rightarrow +\infty$. If $-x_n \rightarrow +\infty$, we say that $x_n \rightarrow -\infty$.

Definition III.3.3. Let $(x_n)_{n \in \mathbb{N}} \subseteq \mathbb{R}$. Let $E \subseteq \bar{\mathbb{R}}$ denote the set of subsequential limits of $(x_n)_n$ in the extended real line. The supremum of E is called the *upper limit* or *limit superior* of $(x_n)_n$, and is denoted by $\limsup_{n \rightarrow \infty} x_n$.

The infimum of E is called the *lower limit* or *limit inferior* of $(x_n)_n$, denoted $\liminf_{n \rightarrow \infty} x_n$.

Example. Let $(x_n = (-1)^n)_{n \in \mathbb{N}}$. Then $E = \{-1, +1\}$ so $\limsup_{n \rightarrow \infty} x_n = 1$ and $\liminf_{n \rightarrow \infty} x_n = -1$.

Lecture 17.

Thursday

February 08

Theorem III.3.4. Let $(x_n)_{n \in \mathbb{N}} \subseteq \mathbb{R}$ be a sequence and E be the set of subsequential limits of $(x_n)_n$ in $\overline{\mathbb{R}}$.

- (1) E is non-empty.
- (2) $\sup E$ and $\inf E$ are contained in E .
- (3) If $x > \sup E$ (resp. $x < \inf E$), then there is an $N \in \mathbb{N}$ such that for all $n \geq N$, $x_n < x$ (resp. $x_n > x$).
- (4) $\sup E$ (resp. $\inf E$) is the only element of $\overline{\mathbb{R}}$ satisfying both (2) and (3).

Proof. (1) If $(x_n)_n$ is bounded, then E is non-empty by theorem III.1.5.

Let $(x_n)_{n \in \mathbb{N}}$ be unbounded above. Let $n_0 = 0$, and for $k \geq 0$, let

$$n_{k+1} = \min\{n > n_k \mid x_n > x_{n_k}\}$$

This exists since $(x_n)_n$ is unbounded above.

Suppose $m \notin (n_k)_{k \in \mathbb{N}}$. Let k be such that $n_k < m < n_{k+1}$. $x_m > x_{n_k}$ would imply $n_{k+1} \leq m$, so $x_m \leq x_{n_k}$. This shows that each x_m not in the subsequence is bounded above by some element of the subsequence.

Thus $(x_{n_k})_k$ is unbounded above, for if it weren't, all of $(x_n)_n$ would be bounded above. So for every $M \in \mathbb{R}$, there is a K such that $x_{n_K} > M$, but since the subsequence is increasing, $x_{n_k} > M$ for all $k \geq K$. Thus $\lim x_{n_k} = +\infty$.

(2) If $\sup E = +\infty$, then for all $M \in \mathbb{R}$, there is an $e_M \in E$ larger than $M + 1$, so there is some x_n larger than M . Thus $(x_n)_n$ is unbounded above, so by the previous argument, $+\infty \in E$.

Now suppose $\sup E = x \in \mathbb{R}$. Let $\varepsilon_n = \frac{1}{2n}$. Let $n_0 = 0$. For $k > 0$, let e_k be an element of E larger than $x - \varepsilon_k$. Let $n_k > n_{k-1}$ be such that $x_{n_k} \in (e_k - \varepsilon_k, e_k + \varepsilon_k)$. Then $|x_{n_k} - x| < 2\varepsilon_k = \frac{1}{k}$. Thus $x_{n_k} \rightarrow x$, so $x \in E$. \square

Example. Let $(x_n)_{n \in \mathbb{N}}$ be an enumeration of \mathbb{Q} . Then $E = \overline{\mathbb{R}}$.

Proof. Let $x \in \mathbb{R}$. Then for any $\varepsilon > 0$, there are infinitely many rationals that are ε -close to x . Thus $x \in E$.

For $x = \pm\infty$, replace “ ε -close” with “larger/smaller than M ”. \square

Theorem III.3.5.

(1) Suppose $x_n \leq y_n$ for all $n \in \mathbb{N}$. Then

$$\liminf x_n \leq \liminf y_n \quad \text{and} \quad \limsup x_n \leq \limsup y_n.$$

(2) $\lim x_n = x$ iff $\limsup x_n = \liminf x_n = x$.

Proof of theorem III.3.4 (continued). Let $\alpha^* = \sup E$.

(3) Suppose not. Let $x > \sup E$ such that for every $k \in \mathbb{N}$, there exists an $m(k) \geq k$ such that $x_{m(k)} \geq x$. Let $n_0 = m(0)$, and for $l \geq 1$, let $n_k = m(n_{k-1} + 1)$. Then $n_0 < n_1 < n_2 < \dots$ and $x_{n_k} \geq x$ for all k . Thus $\gamma = (x_{n_k})_k$ is a subsequence of $(x_n)_n$, but all subsequential limits of γ are at least $x > \sup E$. But a subsequential limit of γ is a subsequential limit of $(x_n)_n$, so $\sup E \geq x$, a contradiction.

(4) Suppose $y < z$ in $\bar{\mathbb{R}}$ satisfy both (2) and (3). That is, both y and z are sequential limits of $(x_n)_n$, and if $x > y$ (or $x > z$), then there exists an $N \in \mathbb{N}$ such that $x_n < x$ for all $n \geq N$.

Choose

$$x = \begin{cases} 0 & \text{if } y = -\infty, z = +\infty \\ z - 1 & \text{if } y = -\infty, z \in \mathbb{R} \\ y + 1 & \text{if } y \in \mathbb{R}, z = +\infty \\ \frac{y+z}{2} & \text{if } y, z \in \mathbb{R} \end{cases}$$

In each case, $y < x < z$. By (3) applied to x , all but finitely many x_n are less than x . By (2) applied to z , infinitely many x_n are greater than x . Contradiction.

□

Lecture 18.

Monday

February 12

Theorem III.3.6.

(1) The following sequences admit limits in $\overline{\mathbb{R}}$.

$$y_n = \sup\{x_k : k \geq n\}$$

$$z_n = \inf\{x_k : k \geq n\}$$

(2) Moreover,

$$\limsup_{n \rightarrow \infty} x_n = \lim_{n \rightarrow \infty} y_n$$

$$\liminf_{n \rightarrow \infty} x_n = \lim_{n \rightarrow \infty} z_n$$

where limits are taken in $\overline{\mathbb{R}}$.

Remark. Let $(A_n)_{n \in \mathbb{N}}$ be a sequence of subsets of X . Define

$$A^* = \limsup_{n \rightarrow \infty} A_n = \bigcap_{n \in \mathbb{N}} \bigcup_{k \geq n} A_k$$

$$A_* = \liminf_{n \rightarrow \infty} A_n = \bigcup_{n \in \mathbb{N}} \bigcap_{k \geq n} A_k$$

Then $x \in A^*$ iff x is in infinitely many A_n , and $x \in A_*$ iff x is in all but finitely many A_n .

We say that $(A_n)_{n \in \mathbb{N}}$ *converges* if $A^* = A_*$.

We can characterize this using indicator functions.

$$\mathbf{1}_{A^*} = \limsup_{n \rightarrow \infty} \mathbf{1}_{A_n}$$

$$\mathbf{1}_{A_*} = \liminf_{n \rightarrow \infty} \mathbf{1}_{A_n}$$

which is to say that for each $x \in X$,

$$\mathbf{1}_{A^*}(x) = \limsup_{n \rightarrow \infty} \mathbf{1}_{A_n}(x)$$

$$\mathbf{1}_{A_*}(x) = \liminf_{n \rightarrow \infty} \mathbf{1}_{A_n}(x)$$

Proof. $(y_n)_n$ is a decreasing sequence, so it has a limit in $\overline{\mathbb{R}}$, since if it is not bounded, it converges to $-\infty$.

Let $y = \lim_{n \rightarrow \infty} y_n$. Since (y_n) is decreasing, given $k \in \mathbb{N}$, there exists an

$N(k) \in \mathbb{N}$ such that for all $n \geq N(k)$,

$$y \leq y_n < y + \frac{1}{k}.$$

But $y_n = \sup\{x_i : i \geq n\}$, so for all $n \geq N(k)$, there exists an $m(k, n)$ such that $y_n - \frac{1}{k} < x_{m(k, n)} \leq y_n$.

Let

$$\begin{aligned} n_1 &= m(1, N(1)) \\ n_2 &= m(2, n_1 \vee N(2) + 1) > n_1 \vee N(2) \\ &\vdots \\ n_k &= m(k, n_{k-1} \vee N(k) + 1) > n_{k-1} \vee N(k) \end{aligned}$$

□

Assignment 5

For quiz on 1
Mar 2024

Problem 3.1. Let $(x_n)_{n \in \mathbb{N}}$ be a convergent sequence in \mathbb{R} , with $x_n \geq 0$ for all $n \in \mathbb{N}$. Let $k \in \mathbb{N}^*$. Show that

$$\lim_{n \rightarrow \infty} (x_n)^{1/k} = \left(\lim_{n \rightarrow \infty} x_n \right)^{1/k}.$$

Solution. Call the limit of $(x_n)_n$ L . Let $\varepsilon > 0$ and let $\varepsilon' = \frac{\varepsilon}{L^{1/k}}$. Then for sufficiently small ε' ,

$$(L^{1/k} - \varepsilon)^k \leq L(1 - k\varepsilon' + 2^k(\varepsilon')^2) < L$$

$$(L^{1/k} + \varepsilon)^k \geq L(1 + k\varepsilon') > L$$

But $x_n \rightarrow L$, so eventually $x_n \in (L(1 - k\varepsilon' + 2^k(\varepsilon')^2), L(1 + k\varepsilon'))$. Then $x_n^{1/k} \in (L^{1/k} - \varepsilon, L^{1/k} + \varepsilon)$. ■

Solution (Alternative). Let $L = \lim_{n \rightarrow \infty} x_n$. Then $\frac{x_n}{L} \rightarrow 1$. But notice that for any real $a > 0$,

$$|1 - a^{1/k}| \leq |1 - a|$$

because $x^k - 1 = (x - 1)(x^{k-1} + x^{k-2} + \cdots + 1)$ where the second term is obviously larger than 1.

But then

$$\left(\frac{x_n}{L} \right)^{1/k} \rightarrow 1$$

which proves the result. ■

Problem 3.2. Let (X, d) be a complete metric space, and $Y \subseteq X$. Show that $(Y, d|_Y)$ is a complete metric space if and only if Y is closed in (X, d) .

Solution. Y is a complete metric space iff every Cauchy sequence in Y converges in Y . But X is complete, so every Cauchy sequence in Y converges in X . Thus, Y is complete iff every convergent sequence in Y (viewed as a sequence in X) converges in Y . This is true iff Y is closed in X . ■

Problem 3.3. Let (X, d) be a metric space and $A \subseteq X$ be a dense subset, i.e., $\bar{A} = X$. Show that if every Cauchy sequence in A converges to a limit in X , then X is a complete metric space.

Solution. Let $(x_n)_n$ be a Cauchy sequence in X . For each $n \in \mathbb{N}$, there exists $a_n \in A$ such that $d(x_n, a_n) < \frac{1}{n}$. Then $(a_n)_n$ is a Cauchy sequence in A , so it converges to some $a \in X$. But $d(x_n, a_n) \rightarrow 0$, so $x_n \rightarrow a$. ■

Problem 3.4. For any real sequences $(x_n)_{n \in \mathbb{N}}$ and $(y_n)_{n \in \mathbb{N}}$ show that

$$\begin{aligned}\limsup_{n \rightarrow \infty} (x_n + y_n) &\leq \limsup_{n \rightarrow \infty} x_n + \limsup_{n \rightarrow \infty} y_n, \\ \liminf_{n \rightarrow \infty} (x_n + y_n) &\geq \liminf_{n \rightarrow \infty} x_n + \liminf_{n \rightarrow \infty} y_n.\end{aligned}$$

Solution. Let $X = \limsup_{n \rightarrow \infty} x_n$ and $Y = \limsup_{n \rightarrow \infty} y_n$. Then for any $z > X + Y$, rewrite z as $(X + \delta) + (Y + \delta) + \delta$. Then there is an N such that for all $n \geq N$,

$$x_n < X + \delta \quad \text{and} \quad y_n < Y + \delta$$

so that

$$x_n + y_n < z - \delta.$$

But then $z - \delta$ cannot be a subsequential limit of $(x_n + y_n)_n$. Thus

$$\limsup_{n \rightarrow \infty} x_n + y_n \leq X + Y. \quad \blacksquare$$

Problem 3.5. Compute $\limsup_{n \rightarrow \infty} x_n$ and $\liminf_{n \rightarrow \infty} x_n$, where the sequence $(x_n)_{n \in \mathbb{N}^*} \subseteq \mathbb{R}$ is given by

$$\begin{aligned}x_1 &= 0, \\ x_{2m} &= \frac{x_{2m-1}}{2}, \quad m \geq 1, \\ x_{2m+1} &= \frac{1}{2} + x_{2m}, \quad m \geq 1.\end{aligned}$$

Solution. **Claim:** $x_{2m+1} = 1 - \frac{1}{2^m}$.

Proof. Induction. □

Corollary: $x_{2m} = \frac{1}{2} - \frac{1}{2^m}$.

Thus $\inf_{n \geq 2m} x_n = x_{2m}$. Then

$$\liminf_{n \rightarrow \infty} x_n = \lim_{n \rightarrow \infty} \left(\frac{1}{2} - \frac{1}{2^n} \right) = \frac{1}{2}.$$

For limsup, note that each term is less than 1, but 1 is a subsequential limit via the odd terms. Thus

$$\limsup_{n \rightarrow \infty} x_n = 1.$$

III.4 Series

Lecture 19.

Monday

February 26

We have seen infinite sums already, in the form of decimal expansions, and also in computing the “length” of the Cantor set.

Definition III.4.1. Let $(a_n)_{n \in \mathbb{N}} \subseteq \mathbb{C}$. We say that the infinite sum

$$\sum_{n=0}^{\infty} a_n$$

converges to a iff the sequence of partial sums $(S_n)_{n \in \mathbb{N}}$ given by

$$\begin{aligned} S_0 &= a_0 \\ S_1 &= a_0 + a_1 \\ &\vdots \\ S_n &= a_0 + a_1 + \cdots + a_n \end{aligned}$$

converges to a . In that case, a is said to be the sum of the given series. If $(S_n)_n$ diverges, then the series is said to diverge.

Example. Let $z \in \mathbb{C}$. Let $a_n = z^n$ for $n \in \mathbb{N}$. We wish to compute $\sum_{n=0}^{\infty} z^n$. Note that

$$\begin{aligned} S_n &= z^0 + z^1 + \cdots + z^n \\ \implies (1 - z)S_n &= 1 - z^{n+1} \end{aligned}$$

so if $z \neq 1$,

$$S_n = \frac{1 - z^{n+1}}{1 - z}$$

We have three cases:

- If $|z| < 1$, then $\lim_{n \rightarrow \infty} |z|^{n+1} = 0$. So by the algebra of limits, $\lim_{n \rightarrow \infty} S_n = \frac{1}{1-z}$ so that the series converges to $\frac{1}{1-z}$. Here, we have used that for any complex sequence $(z_n)_n$, $z_n \rightarrow 0$ iff $|z_n| \rightarrow 0$.
- If $|z| > 1$, then $\lim_{n \rightarrow \infty} z^{n+1}$ does not exist, so the series diverges. So by the algebra of limits, $\lim_{n \rightarrow \infty} S_n$ does not exist.
- For $|z| = 1$, we consider a few special cases first.
 - If $z = 1$, then $S_n = n + 1 \rightarrow \infty$.

– If $z = -1$, then $S_n = \mathbf{1}_{n \text{ is even}}$ which is divergent.

Even for the general case, we can use theorem III.4.2 to conclude that the series diverges, since $z^n \not\rightarrow 0$.

Theorem III.4.2. *Let $(a_n)_{n \in \mathbb{N}} \subseteq \mathbb{C}$. Then*

- (1) $\sum_{n=0}^{\infty} a_n$ converges iff for every $\varepsilon > 0$, there exists an $N \in \mathbb{N}$ such that for all $n > m \geq N$, we have that $\left| \sum_{j=m}^{n-1} a_j \right| < \varepsilon$.
- (2) If $\sum_{n=0}^{\infty} a_n$ converges, then $\lim_{n \rightarrow \infty} a_n = 0$.
- (3) Suppose $a_n \geq 0$ (a_n is real). Then $\sum_{n=0}^{\infty} a_n$ converges iff the sequence of partial sums is bounded above.

Proof.

- (1) The metric space $(\mathbb{C}, |\cdot|) \cong (\mathbb{R}^2, \|\cdot\|)$ is complete, so we can use the Cauchy criterion for convergence applied to the sequence of partial sums.
- (2) From (1) using $n = m + 1$.
- (3) Monotone convergence theorem applied to the SOPS. □

Theorem III.4.3 (Cauchy condensation test). *Let $a_1 \geq a_2 \geq \dots \geq 0$. Then $\sum_{n=1}^{\infty} a_n$ converges iff $\sum_{n=1}^{\infty} 2^n a_{2^n}$ converges.*

Proof. Let the SOPS of the two series be $(S_n)_{n \geq 1}$ and $(T_n)_{n \geq 1}$ respectively. Note that we only need to show that $(S_n)_n$ is bounded above iff $(T_n)_n$ is.

Let k and n be such that $n \leq 2^k$. Then

$$\begin{aligned} S_n &= a_1 + a_2 + a_3 + \dots + a_n \\ &\leq a_1 + (a_2 + a_3) + \dots + (a_{2^k} + \dots + a_{2^{k+1}-1}) \\ &\leq a_1 + 2a_2 + \dots + 2^k a_{2^k} \\ &= T_k \end{aligned}$$

Thus if $(T_n)_n$ is bounded then so is $(S_n)_n$.

Lecture 20.
Wednesday
February 28

Now let $2^k < n$. Then

$$\begin{aligned}
 S_n &= a_1 + a_2 + a_3 + \cdots + a_n \\
 &\geq a_1 + a_2 + a_3 + \cdots + a_{2^k} \\
 &= a_1 + a_2 + (a_3 + a_4) + \cdots + (a_{2^{k-1}+1} + a_{2^k}) \\
 &\geq a_1/2 + a_2 + 2a_4 + \cdots + 2^{k-1}a_{2^k} \\
 &= \frac{1}{2}(a_1 + 2a_2 + 4a_4 + \cdots + 2^k a_{2^k}) \\
 &= T_k
 \end{aligned}$$

Thus if $(S_n)_n$ is bounded then so is $(T_n)_n$. □

Corollary III.4.4. $\sum_{n=1}^{\infty} \frac{1}{n^p}$ is convergent iff $p > 1$.

Proof. If $p \leq 0$, $\frac{1}{n^p} \not\rightarrow 0$, so the series cannot converge. If $p > 0$, then $\frac{1}{n^p}$ is decreasing and non-negative, so by the Cauchy condensation test, this converges iff $\sum_{n=1}^{\infty} 2^n \frac{1}{(2^n)^p}$ converges. But this is a geometric series with ratio 2^{1-p} . This converges iff $2^{1-p} < 1 \iff p > 1$. □

Corollary III.4.5. $\sum_{n=2}^{\infty} \frac{1}{n(\log n)^p}$ converges iff $p > 1$.

Proof. If $p \leq 0$, then the series is bounded below by $\frac{1}{n}$ for $n \geq 3$. So by the comparison test, the series diverges.

For $p > 0$, the terms are decreasing and non-negative. $\sum_{n=1}^{\infty} \frac{2^n}{2^n n^p (\log 2)^p}$ converges iff $p > 1$ by the previous corollary. □

Recall that in UMA101 we defined e as $\sum_{n=0}^{\infty} \frac{1}{n!}$.

Theorem III.4.6. $e = \lim_{n \rightarrow \infty} (1 + \frac{1}{n})^n$.

Proof. Let $s_n = \sum_{j=0}^n \frac{1}{j!}$ and $t_n = (1 + \frac{1}{n})^n$.

$$\begin{aligned}
 t_n &= \sum_{j=0}^n \binom{n}{j} \frac{1}{n^j} \\
 &= \sum_{j=0}^n \frac{1}{j!} \frac{n(n-1)\cdots(n-j+1)}{n^j} \\
 &= 1 + 1 + \frac{1}{2!} \left(1 - \frac{1}{n}\right) + \frac{1}{3!} \left(1 - \frac{1}{n}\right) \left(1 - \frac{2}{n}\right) + \cdots + \\
 &\quad \frac{1}{n!} \left(1 - \frac{1}{n}\right) \cdots \left(1 - \frac{n-1}{n}\right)
 \end{aligned}$$

which clearly shows that $t_n \leq s_n$ so $\limsup_{n \rightarrow \infty} t_n \leq e$.

Fix $m \in \mathbb{N}$. For all $n \geq m \geq 3$,

$$\begin{aligned} \liminf_{n \rightarrow \infty} &\geq 1 + 1 + \frac{1}{2!} \left(1 - \frac{1}{n}\right) + \cdots + \\ &\quad \frac{1}{m!} \left(1 - \frac{1}{n}\right) \left(1 - \frac{2}{n}\right) \cdots \left(1 - \frac{m-1}{n}\right) \\ &\xrightarrow[m \text{ fixed}]{n \rightarrow \infty} 1 + 1 + \frac{1}{2!} + \cdots + \frac{1}{m!} \\ &= S_m \end{aligned}$$

As $m \rightarrow \infty$,

$$\liminf_{n \rightarrow \infty} t_n \geq \lim_{m \rightarrow \infty} S_m = e$$

□

Definition III.4.7 (Formal power series). Let $(c_n)_{n \in \mathbb{N}} \subseteq \mathbb{C}$. Then the formal sum

$$\sum_{n=0}^{\infty} c_n z^n$$

is called a *power series*. Here, z is an arbitrary complex number, and the convergence of this series depends on z .

Examples.

- $\sum_{n=0}^{\infty} \frac{z^n}{n!}$ converges everywhere.
- $\sum_{n=0}^{\infty} z^n$ converges nowhere on $|z| = 1$.
-

Lecture 21.

III.4.1 Combining Series

Theorem III.4.8. For $\sum_{n=0}^{\infty} a_n$ and $\sum_{n=0}^{\infty} b_n$ convergent to a and b respectively,

- (i) (Addition) $\sum (a_n + b_n)$ converges to $a + b$,
- (ii) (Scalar product) $\sum c a_n$ converges to $c a$ for any $c \in \mathbb{C}$,
- (iii) (Termwise product) $\sum a_n b_n$ need not converge.

Proof. The first two parts are trivial. For the third, consider the series $\sum_{n=1}^{\infty} \frac{(-1)^n}{\sqrt{n}}$, which converges by the alternating series test. However, taking its termwise product with itself gives $\sum_{n=1}^{\infty} \frac{1}{n}$, which diverges. \square

Definition III.4.9 (Absolute convergence). A series $\sum_{n=0}^{\infty} a_n$ is said to be *absolutely convergent* if $\sum_{n=0}^{\infty} |a_n|$ converges. If it converges but not absolutely, it is said to be *conditionally convergent*.

The counterexample in the proof of the theorem is an example of a conditionally convergent series.

Theorem III.4.10. Let $(a_n)_{n \in \mathbb{N}} \subseteq \mathbb{C}$ and $(b_n)_{n \in \mathbb{N}} \subseteq \mathbb{R}$. Suppose that the SOPS of $\sum_{n=0}^{\infty} a_n$ is bounded, and that $b_1 \geq b_2 \geq \dots$ with $b_n \rightarrow 0$. Then $\sum_{n=0}^{\infty} a_n b_n$ converges.

Proof. Let $(A_n)_n < M$ be the SOPS of $\sum_{n=0}^{\infty} a_n$. Then for any $p < q$,

$$\begin{aligned}
 \sum_{n=p}^q a_n b_n &= \sum_{n=p}^q (A_n - A_{n-1}) b_n \\
 &= \sum_{n=p}^q A_n b_n - \sum_{n=p}^q A_{n-1} b_n \\
 &= \sum_{n=p}^q A_n b_n - \sum_{n=p-1}^{q-1} A_n b_{n+1} \\
 &= A_q b_q - A_{p-1} b_p + \sum_{n=p}^{q-1} A_n (b_n - b_{n+1})
 \end{aligned}$$

Taking absolute values,

$$\begin{aligned}
 \left| \sum_{n=p}^q a_n b_n \right| &\leq |A_q| b_q + |A_{p-1}| b_p + \sum_{n=p}^{q-1} |A_n| (b_n - b_{n+1}) \\
 &\leq M b_q + M b_p + \sum_{n=p}^{q-1} M (b_n - b_{n+1}) \\
 &= M(b_p + b_q) + M(b_p - b_q) \\
 &= 2M b_p
 \end{aligned}$$

Since $b_n \rightarrow 0$, $2Mb_p < \varepsilon$ for sufficiently large p . Thus $\sum_{n=0}^{\infty} a_n b_n$ converges by the Cauchy criterion. \square

Remarks.

- If $\sum a_n$ converges, then the condition on the SOPS is satisfied. But the condition on the b_n is much more special.
- The alternating series test is a special case of this theorem, with $a_n = (-1)^n$ and b_n decreasing to 0.
- Suppose $(b_n)_n$ is as in the theorem, and $\sum b_n z^n$ has radius of convergence 1. Then it converges for all $|z| = 1$, except possibly at $z = 1$. This is because $\sum_{n=0}^{\infty} z^n$ has bounded sops for each $|z| = 1$, $z \neq 1$.

Proof. Let $(Z_n)_n$ be the sops. Since $z \neq 1$, $Z_n = \frac{1-z^{n+1}}{1-z}$. The numerator is bounded by 2, and the denominator is constant. \square

Corollary III.4.11 (Alternating series test). *Let $(a_n)_{n \in \mathbb{N}} \subseteq \mathbb{R}$ be decreasing to 0. Then $\sum_{n=0}^{\infty} (-1)^n a_n$ converges.*

Definition III.4.12. Given two formal series $\sum_{n \in \mathbb{N}} a_n$ and $\sum_{n \in \mathbb{N}} b_n$, their *Cauchy product* is the series $\sum_{n \in \mathbb{N}} c_n$ where

$$c_n = \sum_{k=0}^n a_k b_{n-k}$$

This is motivated by the termwise product of power series.

If $\sum_{n \in \mathbb{N}} a_n$ and $\sum_{n \in \mathbb{N}} b_n$ converge, does $\sum_{n \in \mathbb{N}} c_n$ have to converge?

Lecture 22.

Monday

March 04

No. Take the conditionally convergent series $a_n = b_n = \frac{(-1)^n}{\sqrt{n}}$. Then

$$\begin{aligned} c_n &= \sum_{k=1}^n a_k b_{n+1-k} \\ &= \sum_{k=1}^n \frac{(-1)^{n+1}}{\sqrt{k}\sqrt{n+1-k}} \\ |c_n| &= \sum_{k=1}^n \frac{1}{\sqrt{k}\sqrt{n+1-k}} \\ &\geq \sum_{k=1}^n \frac{1}{\sqrt{n}\sqrt{n}} \\ &= \frac{n}{n} = 1. \end{aligned}$$

Thus $\sum_{n \in \mathbb{N}} c_n$ cannot converge.

Theorem III.4.13 (Mertens). *Suppose that*

- (i) $\sum_{n \in \mathbb{N}} a_n$ converges absolutely to A , and
- (ii) $\sum_{n \in \mathbb{N}} b_n$ converges to B .

Then their Cauchy product $\sum_{n \in \mathbb{N}} c_n$ converges to AB .

Proof. Let $(A_n)_{n \in \mathbb{N}}$, $(B_n)_{n \in \mathbb{N}}$ and $(C_n)_{n \in \mathbb{N}}$ be the sops of $\sum a_n$, $\sum b_n$ and $\sum c_n$ respectively.

$$\begin{aligned} C_n &= c_0 + c_1 + \cdots + c_n \\ &= a_0 b_0 + (a_0 b_1 + a_1 b_0) + \cdots + (a_0 b_n + \cdots + a_n b_0) \\ &= a_0 B_n + a_1 B_{n-1} + \cdots + a_n B_0 \\ &= A_n B + (a_0(B_n - B) + \cdots + a_n(B_0 - B)). \end{aligned}$$

Introduce the notation β_k for $B_k - B$.

$$= A_n B + (a_0 \beta_n + \cdots + a_n \beta_0).$$

Define $\delta_n = a_0 \beta_n + \cdots + a_n \beta_0$. It suffices to show that

$$\lim_{n \rightarrow \infty} \delta_n = 0.$$

Let $\alpha = \sum_{n \in \mathbb{N}} |a_n|$. Since $\lim_{n \rightarrow \infty} \beta_n = 0$, we have that for every $\epsilon > 0$, there exists $m \in \mathbb{N}$ such that $|\beta_n| < \epsilon$ for all $n \geq m$.

Fix an $\varepsilon > 0$ and choose an appropriate m . Then for $n \geq m$,

$$\begin{aligned} |\delta_n| &= |a_0\beta_n + \cdots + a_n\beta_0| \\ &= |a_0\beta_n + \cdots + a_{n-(m-1)}\beta_{m-1}| + \varepsilon \sum_{j=m}^n |a_j| \end{aligned}$$

Taking limit as $n \rightarrow \infty$,

$$\limsup_{n \rightarrow \infty} |\delta_n| \leq \varepsilon \alpha.$$

Since ε was arbitrary, we have that $\limsup_{n \rightarrow \infty} |\delta_n| = 0$ and so $|\delta_n| \rightarrow 0$. This gives $\delta_n \rightarrow 0$ so that $C_n = A_n B + \delta_n \rightarrow AB$. \square

III.5 Rearrangements

Conditionally convergent real series have the remarkable feature that their terms can be rearranged to converge to any real number.

Example. Consider the series $\sum \frac{(-1)^n}{n}$. Let $(S_n)_{n \in \mathbb{N}^*}$ be its partial sums. Note that $S_3 > S_4, S_5, S_6, \dots$. So the limit is less than $1 - \frac{1}{2} + \frac{1}{3} = \frac{5}{6}$.

Now consider the rearranged series

$$1 + \frac{1}{3} - \frac{1}{2} + \frac{1}{5} + \frac{1}{7} - \frac{1}{4} + \frac{1}{9} + \frac{1}{11} - \frac{1}{6} + \dots$$

We can show that this converges, by rewriting it as

$$1 + \frac{1}{3} - \frac{2}{4} + \frac{1}{5} + \frac{1}{7} - \frac{2}{8} + \frac{1}{9} + \frac{1}{11} - \frac{2}{12} + \dots$$

and applying theorem [III.4.10](#) to

$$\begin{aligned} (a_n)_{n \in \mathbb{N}} &= (1, 1, -2, 1, 1, -2, 1, 1, -2, \dots) \\ (b_n)_{n \in \mathbb{N}} &= \left(1, \frac{1}{3}, \frac{1}{4}, \frac{1}{5}, \frac{1}{7}, \frac{1}{8}, \frac{1}{9}, \frac{1}{11}, \frac{1}{12}, \dots\right) \end{aligned}$$

Grouping terms in groups of three, we notice that each group is positive. So the rearranged series converges to a number greater than $1 + \frac{1}{3} - \frac{1}{2} = \frac{5}{6}$. Thus rearranging the terms has created a series that has a different sum.

Chapter IV

Functional Limits & Continuity

Lecture 23.

Wednesday

March 06

IV.1 Definitions

Definition IV.1.1 (Limit). Let $f: E \rightarrow Y$ be a function from a subset E of a metric space (X, d_X) to another metric space (Y, d_Y) . Let $p \in X$ be a limit point of E . We say that

$$\lim_{x \rightarrow p} f(x) = q \in Y$$

if for every $\varepsilon > 0$, there exists a $\delta > 0$ such that whenever $0 < d_X(x, p) < \delta$ and $x \in E$, then $d_Y(f(x), q) < \varepsilon$.

Remarks.

- p need not be in E , i.e., f need not be defined at p .
- Even if f is defined at p , we are not requiring that $f(p) = q$. For example, consider the function $f: \mathbb{R} \rightarrow \mathbb{R}$ defined by

$$f(x) = 0^{0^{x^2}}.$$

Then $\lim_{x \rightarrow 0} f(x) = 1$ even though $f(0) = 0$.

Theorem IV.1.2 (Sequential characterization of limits). *Let X, Y, E, f and p be as in definition IV.1.1. Then*

$$\lim_{x \rightarrow p} f(x) = q$$

if and only if for every sequence $(p_n)_{n \in \mathbb{N}} \subseteq E \setminus \{p\}$ such that $p_n \rightarrow p$, we have $f(p_n) \rightarrow q$.

Proof. Suppose that $\lim_{x \rightarrow p} f(x) = q$. Let $(p_n)_{n \in \mathbb{N}} \subseteq E \setminus \{p\} \rightarrow p$. Let $\varepsilon > 0$. Then there exists a $\delta > 0$ such that whenever $d_X(x, p) < \delta$ and $x \in E \setminus \{p\}$, then $d_Y(f(x), q) < \varepsilon$.

But since $(p_n)_{n \in \mathbb{N}} \rightarrow p$, there exists an $N \in \mathbb{N}$ such that for all $n \geq N$, $d_X(p_n, p) < \delta$. So for all $n \geq N$, $d_Y(f(p_n), q) < \varepsilon$, which proves that $f(p_n) \rightarrow q$.

For the converse, we will prove the contrapositive. Now suppose that $\lim_{x \rightarrow p} f(x) \neq q$. That is, there is an $\varepsilon > 0$ such that for every $\delta > 0$, there exists a $p_\delta \in E$ such that $0 < d_X(p_\delta, p) < \delta$ but $d_Y(f(p_\delta), q) \geq \varepsilon$.

Consider the sequence $(p_{\frac{1}{n}})_{n \in \mathbb{N}}$. Then $p_{\frac{1}{n}} \rightarrow p$, but $f(p_{\frac{1}{n}}) \not\rightarrow q$. Thus we have constructed a sequence that does not satisfy the condition in the theorem. \square

Corollary IV.1.3.

(i) *Functional limits are unique.*

(ii) *Let $f, g: E \rightarrow \mathbb{C}$ and p be a limit point of E . Assume that limits $\lim_{x \rightarrow p} f(x) = q$ and $\lim_{x \rightarrow p} g(x) = r$ exist. Then*

$$\begin{aligned}\lim_{x \rightarrow p} (f(x) + g(x)) &= q + r, \\ \lim_{x \rightarrow p} (f(x) - g(x)) &= q - r, \\ \lim_{x \rightarrow p} (f(x) \cdot g(x)) &= q \cdot r, \\ \lim_{x \rightarrow p} (f(x)/g(x)) &= q/r \quad \text{if } r \neq 0.\end{aligned}$$

(iii) *Let $f, g: E \rightarrow \mathbb{R}^m$ and p, q, r be as above. Then*

$$\begin{aligned}\lim_{x \rightarrow p} (f(x) + g(x)) &= q + r, \\ \lim_{x \rightarrow p} \langle f(x), g(x) \rangle &= \langle q, r \rangle\end{aligned}$$

Definition IV.1.4 (Continuity). Let X and Y be metric spaces, $E \subseteq X$ and $f: E \rightarrow Y$. Let $p \in E$. Then we say that f is *continuous at p* if for every $\varepsilon > 0$ there exists a $\delta > 0$ such that for all $x \in E$ with $d_X(x, p) < \delta$, we have $d_Y(f(x), f(p)) < \varepsilon$.

Remarks.

- If p is a limit point of E , then f is continuous at p iff $\lim_{x \rightarrow p} f(x)$ exists and equals $f(p)$.
- If p is an isolated point of E , then any f is continuous at p .

Theorem IV.1.5 (Sequential characterization of continuity). *Let X, Y, E, f and p be as in definition IV.1.4. Then f is continuous at p if and only if for every sequence $(p_n)_{n \in \mathbb{N}} \subseteq E$ converging to p , we have $f(p_n) \rightarrow f(p)$.*

Corollary IV.1.6.

- (i) *Let $f, g: E \rightarrow \mathbb{C}$ and $p \in E$ such that f and g are continuous at p . Then $f + g, f - g, f \cdot g$ and f/g (if $g(p) \neq 0$) are continuous at p .*
- (ii) *Let $f, g: E \rightarrow \mathbb{R}^m$ and p, q, r be as above. Then $f + g$ and $\langle f, g \rangle$ are continuous at p .*

Exercise IV.1.7 (Composition of continuous functions). *Let X, Y, Z be metric spaces and $E \subseteq X$. Let $f: E \rightarrow Y$ and $g: f(E) \rightarrow Z$. If f is continuous at $p \in E$ and g is continuous at $f(p)$, then $g \circ f$ is continuous at p .*

Proof. Let $p \in E$ be as in the statement and let $z = g(f(p))$. Let $\varepsilon > 0$. By continuity of g at $f(p)$, there exists a $\delta > 0$ such that for all $y \in B_{f(E)}(f(p); \delta)$, we have $g(y) \in B_Z(z; \varepsilon)$.

But by the continuity of f at p , there exists a $\delta' > 0$ such that for all $x \in B_E(p; \delta')$, we have $f(x) \in B_{f(E)}(f(p); \delta)$, so that $(g \circ f)(x) \in B_Z(z; \varepsilon)$.

Thus $g \circ f$ is continuous at p . \square

Examples (continuous functions).

- All polynomials $p \in \mathbb{R}[x]$ are continuous.
- All rational functions p/q , where $p, q \in \mathbb{R}[x]$ are continuous.
- The exponential function $\exp: \mathbb{R} \rightarrow \mathbb{R}$ is continuous.
- The logarithm function $\log: (0, \infty) \rightarrow \mathbb{R}$ is continuous.
- $x \in \mathbb{R} \mapsto \log_x(a)$, or simply the reciprocal of \log , is continuous.

Lecture 24.

Thursday

March 07

IV.2 Continuity & Topology

Theorem IV.2.1. *Let (X, d_X) and (Y, d_Y) be metric spaces. Let $f: X \rightarrow Y$ be a function. Then the following are equivalent:*

- (i) f is continuous on X .
- (ii) $f^{-1}(U)$ is open in X for every open set U in Y .
- (iii) $f^{-1}(C)$ is closed in X for every closed set C in Y .

Proof. For (ii) \iff (iii), use that $f^{-1}(Y \setminus C) = X \setminus f^{-1}(C)$.

We now show (i) \iff (ii). Suppose f is continuous on X . Let U be open in Y and $x \in f^{-1}(U)$. Then $f(x) \in U$. Since U is open, there exists an $\varepsilon > 0$ such that $B_Y(f(x); \varepsilon) \subseteq U$. Since f is continuous at x , there exists $\delta > 0$ such that for all $x' \in X$ with $d_X(x, x') < \delta$, $d_Y(f(x), f(x')) < \varepsilon$ so that $f(x') \in U$. Then $B_X(x; \delta) \subseteq f^{-1}(U)$.

Conversely, suppose $f^{-1}(U)$ is open for every open set U in Y . Let $x \in X$ and $\varepsilon > 0$. Choose $U = B_Y(f(x); \varepsilon)$. Then $f^{-1}(U)$ is open, so there exists $\delta > 0$ such that $B_X(x; \delta) \subseteq f^{-1}(U)$. Then for all $x' \in X$ with $d_X(x, x') < \delta$, $d_Y(f(x), f(x')) < \varepsilon$. \square

Remark. Continuous functions need not map open sets to open sets, nor closed sets to closed sets.

$x \mapsto 1$ on \mathbb{R} is continuous, but maps open sets to the closed set $\{1\}$.

$x \mapsto \sin x$ on \mathbb{R} is continuous, but the image of the closed set \mathbb{N}^* doesn't contain 0 (π is irrational), even though it is a limit point of the image.

Theorem IV.2.2 (Compactness). *If $f: X \rightarrow Y$ is continuous and $K \subseteq X$ is compact, then $f(K)$ is compact.*

Proof. Let $\{U_\alpha\}$ be an open cover of $f(K)$. Each $f^{-1}(U_\alpha)$ is open in X by theorem IV.2.1. Each $x \in K$ must be in one of these, since otherwise its image would not be covered. Then $\{f^{-1}(U_\alpha)\}$ is an open cover of K . Let $\{f^{-1}(U_{\alpha_i})\}$ be a finite subcover of K . Then $\{U_{\alpha_i}\}$ is a finite subcover of $f(K)$. \square

Remarks.

- The pre-image of a compact set under a continuous function need not be compact.

Proof. Consider $f: x \in \mathbb{R} \mapsto \sin x \in \mathbb{R}$. Then $f^{-1}(\{0\}) = \mathbb{Z}\pi$ is not compact. \square

- Even if the image of every compact set under a function f is compact, f need not be continuous.

Proof. Dirichlet's function. \square

Lecture 25.

Monday
March 11

Corollary IV.2.3. Any \mathbb{R} -valued continuous function on a compact metric space attains its minimum and maximum.

Corollary IV.2.4. If $f: X \rightarrow Y$ is a bijective continuous map and X is compact, then f^{-1} is also continuous.

Proof. Let $U \subseteq X$ be open. Since X is compact, $X \setminus U$ is compact. Since f is continuous, $f(X \setminus U)$ is compact and hence closed. Since f is bijective, $f(X \setminus U) = Y \setminus f(U)$. Thus $f(U)$ is open.

Thus $(f^{-1})^{-1}$ maps open sets to open sets, so f^{-1} is continuous. \square

Definition IV.2.5 (Bounded). A function $f: X \rightarrow Y$ between metric spaces is said to be *bounded* if $f(X)$ is a bounded set in Y .

Definition IV.2.6 (Uniform continuity). A function $f: X \rightarrow Y$ is said to be *uniformly continuous* if for every $\varepsilon > 0$, there exists a $\delta > 0$ such that for all $x \in X$, $f(B_X(x; \delta)) \subseteq B_Y(f(x); \varepsilon)$.

Exercise IV.2.7. Prove that $x \in (0, 1) \mapsto \frac{1}{x}$ is **not** uniformly continuous.

Proof. Let $\varepsilon = 1$. Suppose there exists a $0 < \delta < 2$ such that for all $x \in (0, 1)$, $\left| \frac{1}{x} - \frac{1}{y} \right| < 1$ whenever $|x - y| < \delta$. But choosing $x = y + \frac{\delta}{2} = \sqrt{\frac{\delta}{2}}$, we have

$$\begin{aligned} \left| \frac{1}{x} - \frac{1}{y} \right| &= \frac{|x - y|}{xy} \\ &= \frac{\delta}{2} \cdot \frac{1}{x(x - \frac{\delta}{2})} \\ &> \frac{\delta}{2} \cdot \frac{1}{x^2} \\ &= 1. \end{aligned}$$

\square

Lecture 26.

Wednesday

March 13

Theorem IV.2.8. *A continuous function on a compact set is uniformly continuous.*

Proof. Let $f: X \rightarrow Y$ be continuous where X is compact.

Let $\varepsilon > 0$ be arbitrary. For each $x \in X$, choose $\delta_x > 0$ such that $f(B_X(x; \delta_x)) \subseteq B_Y(f(x); \varepsilon)$. The collection $\{B_X(x; \frac{1}{2}\delta_x)\}_{x \in X}$ is an open cover of X . Since X is compact, only finitely many of these are needed to cover X . Label the centers x_1, \dots, x_n and the corresponding radii $\frac{\delta_1}{2}, \dots, \frac{\delta_n}{2}$. Let $\delta > 0$ be the smallest of these radii.

Let $p, q \in X$ be such that $d_X(p, q) < \delta$. Then there exists an i such that $d_X(p, x_i) < \frac{\delta_i}{2}$. But $d_X(p, q) < \delta < \frac{\delta_i}{2}$, so $d_X(q, x_i) < \delta_i$ by the triangle inequality.

Thus $f(p)$ and $f(q)$ are both at most ε away from $f(x_i)$, so they are at most 2ε away from each other.

Thus for any $2\varepsilon > 0$, we have produced a $\delta > 0$ such that any points within δ of each other are mapped to points within 2ε of each other. \square

Theorem IV.2.9. *Continuous functions map connected sets to connected sets.*

Proof. Let X be connected and $f: X \rightarrow Y$ continuous. Suppose $f(X)$ is not connected. That is, there exist nonempty sets $A, B \subseteq f(X)$ such that $A \cup B = f(X)$ and $\bar{A} \cap B = A \cap \bar{B} = \emptyset$.

Let $A_* = f^{-1}(A)$ and $B_* = f^{-1}(B)$. They are nonempty since A and B are nonempty and in the range. Also, $X = f^{-1}(f(X)) = f^{-1}(A \cup B) = f^{-1}(A) \cup f^{-1}(B)$. So A_* and B_* cover X .

Recall that f is continuous implies that the preimage of a closed set is closed. $A_* = f^{-1}(A) \subseteq f^{-1}(\bar{A})$, so $\bar{A}_* \subseteq f^{-1}(\bar{A})$.

Then

$$\begin{aligned} \bar{A}_* \cap B_* &\subseteq f^{-1}(\bar{A}) \cap f^{-1}(B) \\ &\subseteq f^{-1}(\bar{A} \cap B) \\ &= f^{-1}(\emptyset) = \emptyset. \end{aligned}$$

Similarly, $A_* \cap \bar{B}_* = \emptyset$.

Thus A_* and B_* are a separation of X , contradicting the connectedness of X . \square

IV.3 Discontinuities of functions on \mathbb{R}

Examples.

- The *Heaviside function* defined by

$$H(x) = \begin{cases} 1 & \text{if } x \geq 0, \\ 0 & \text{if } x < 0. \end{cases}$$

- The *sign function* defined by

$$\operatorname{sgn}(x) = \begin{cases} 1 & \text{if } x > 0, \\ 0 & \text{if } x = 0, \\ -1 & \text{if } x < 0. \end{cases}$$

-

$$x \mapsto \begin{cases} \frac{3x-x^2}{x(x^2+2)} & \text{if } x \neq 0, \\ 0 & \text{if } x = 0. \end{cases}$$

-

$$x \mapsto \begin{cases} \frac{1}{x} & \text{if } x \neq 0, \\ 0 & \text{if } x = 0. \end{cases}$$

-

$$x \mapsto \begin{cases} \sin \frac{1}{x} & \text{if } x \neq 0, \\ 0 & \text{if } x = 0. \end{cases}$$

- The *Dirichlet function*

$$\mathbf{1}_{\mathbb{Q}}(x) = \begin{cases} 1 & \text{if } x \in \mathbb{Q}, \\ 0 & \text{otherwise.} \end{cases}$$

This is discontinuous *everywhere*.

Definition IV.3.1. Given $f: (a, b) \rightarrow \mathbb{R}$ and $c \in (a, b)$, we say that

- (i) f has a *simple discontinuity* or a *discontinuity of the first kind* at c if the left-hand and right-hand limits $\lim_{x \rightarrow c^-} f(x)$ and $\lim_{x \rightarrow c^+} f(x)$ exist but are either unequal, or unequal to $f(c)$.
- (ii) f has a *discontinuity of the second kind* at c if either the left-hand or right-hand limit does not exist.

The first three examples above have simple discontinuities at 0. The last three have discontinuities of the second kind. The third example has a *removable* discontinuity at 0, since both one-sided limits exist and are equal.

Theorem IV.3.2. *Monotone functions do not have discontinuities of the second kind.*

Lecture 27.
Thursday
March 14

Proof. WLOG let $f: (a, b) \rightarrow \mathbb{R}$ be increasing. Let $c \in (a, b)$.

We will show that

$$\lim_{x \uparrow c} f(x) = \sup_{x \in (a, c)} f(x).$$

Let $L^- = \sup_{x \in (a, c)} f(x)$. For any $\varepsilon > 0$, there is some $x \in (a, c)$ such that $L^- - \varepsilon < f(x) \leq L^-$. Choose $\delta = c - x$. Then by monotonicity, for $x' \in (c - \delta, c)$, we have

$$L^- - \varepsilon < f(x) \leq f(x') \leq L^-.$$

Thus, $\lim_{x \uparrow c} f(x) = L^-$. This is sufficient to prove the theorem.

Since $f(c)$ is an upper bound for $\{f(x) \mid x \in (a, c)\}$, we also have $L^- \leq f(c)$. By symmetry,

$$\lim_{x \uparrow c} f(x) \leq f(c) \leq \lim_{x \downarrow c} f(x).$$

□

Corollary IV.3.3. *The set of discontinuities of a monotone function on an interval is at most countable.*

Proof. Let $f: (a, b) \rightarrow \mathbb{R}$ be increasing and let D be its set of discontinuities. We will construct an injection from D to \mathbb{Q} .

For each $c \in D$, we have

$$\lim_{x \uparrow c} f(x) < \lim_{x \downarrow c} f(x),$$

since equality would force them to be equal to $f(c)$. By the density of \mathbb{Q} in \mathbb{R} , map c to some $q_c \in \mathbb{Q}$ between these two limits.

Then for any $c < d \in D$, we have $q_c < q_d$, since

$$q_c < \lim_{x \downarrow c} f(x) \leq \lim_{x \uparrow d} f(x) < q_d.$$

Thus the map is injective. \square

However! Discontinuities being countable does not imply that they cannot be dense.

Example. Let $D \subseteq (0, 1)$ be a dense countable set. Let $\{x_1, x_2, \dots\}$ be an enumeration. Define

$$f(x) = \sum_{n: x_n < x} \frac{1}{2^n}.$$

Chapter V

Differentiation

V.1 Introduction

Lecture 28.

Monday
March 18

Definition V.1.1 (Differentiation). Let $f: (a, b) \rightarrow \mathbb{R}$ and $c \in (a, b)$. We say that f is *differentiable at c* with derivative $f'(c)$ if

$$\lim_{h \rightarrow 0} \frac{f(c+h) - f(c)}{h} = f'(c).$$

We say that f is *differentiable* if it is differentiable at each $c \in (a, b)$, and the map f' is called the *derivative* of f .

Exercise V.1.2. *Differentiability at a point implies continuity at that point.*

Exercise V.1.3. *If $f, g: (a, b) \rightarrow \mathbb{R}$ are differentiable at $c \in (a, b)$, then*

(i) *so is $f + g$ with $(f + g)'(c) = f'(c) + g'(c)$.*

(ii) *so is fg with $(fg)'(c) = f'(c)g(c) + f(c)g'(c)$.*

(iii) *so is f/g with $(f/g)'(c) = \frac{f'(c)g(c) - f(c)g'(c)}{g(c)^2}$, provided $g(c) \neq 0$.*

Exercise V.1.4. Suppose $f: (a, b) \rightarrow \mathbb{R}$ is differentiable at $c \in (a, b)$. Suppose $f((a, b)) \subseteq (p, q)$ and $g: (p, q) \rightarrow \mathbb{R}$ is differentiable at $f(c)$. Then $g \circ f$ is differentiable at c and

$$(g \circ f)'(c) = g'(f(c))f'(c).$$

Proof. Call a point $x \neq c$ such that $f(x) = f(c)$ a ‘bro’ of c .

Let $(x_n)_{n \in \mathbb{N}} \subseteq (a, b) \setminus \{c\}$ be an (eventually) bro-free sequence converging to c . Then

$$\begin{aligned} \lim_{n \rightarrow \infty} \frac{g(f(x_n)) - g(f(c))}{x_n - c} &= \lim_{n \rightarrow \infty} \frac{g(f(x_n)) - g(f(c))}{f(x_n) - f(c)} \frac{f(x_n) - f(c)}{x_n - c} \\ &= g'(f(c))f'(c). \end{aligned}$$

We have two cases for sequences $(x_n)_n \subseteq (a, b) \setminus \{c\}$ converging to c .

- If there is a neighbourhood of c that contains no bros, then all such sequences are eventually bro-free. Thus by sequential characterization of limits, $(g \circ f)'(c) = g'(f(c))f'(c)$.
- If every neighbourhood of c contains a bro, then $f'(c) = 0$. A bro-free sequence will give the above limit as $g'(f(c))f'(c) = 0$. A bro-only sequence will make the above limit 0. A mix of these can be split into a bro-only sequence and a bro-free sequence, both of which have limit 0.

Thus by sequential characterization of limits,

$$(g \circ f)'(c) = 0 = g'(f(c))f'(c). \quad \square$$

Recall that derivatives are not very well-behaved!

Example. Let

$$f(x) = \begin{cases} x^2 \sin \frac{1}{x} & \text{if } x \neq 0, \\ 0 & \text{if } x = 0. \end{cases}$$

We show that f is differentiable on \mathbb{R} , but f' is discontinuous at 0.

Proof. When $x \neq 0$, we use the fact that polynomials and trigonometric functions are differentiable, so that

$$f'(x) = 2x \sin \frac{1}{x} - \cos \frac{1}{x}.$$

At $x = 0$, we have

$$\lim_{h \rightarrow 0} \frac{f(h) - f(0)}{h} = \lim_{h \rightarrow 0} h \sin \frac{1}{h} = 0.$$

Thus the derivative is well-defined with

$$f'(x) = \begin{cases} 2x \sin \frac{1}{x} - \cos \frac{1}{x} & \text{if } x \neq 0, \\ 0 & \text{if } x = 0. \end{cases} \quad \square$$

V.2 Mean Value Theorems & Applications

Theorem V.2.1. *Let $f: [a, b] \rightarrow \mathbb{R}$ be a function. Suppose f attains a local extremum at $c \in (a, b)$ and f is differentiable at c . Then $f'(c) = 0$.*

Proof. Suppose WLOG that f attains a local maximum at c . Then we have $f(c) \geq f(x)$ for all x close to c . But then for $h > 0$,

$$\frac{f(c+h) - f(c)}{h} \leq 0$$

and

$$\frac{f(c-h) - f(c)}{-h} \geq 0.$$

If the left hand and right hand limits of the difference quotient exist and are equal, then they must both be zero. \square

Exercise V.2.2. *Let $f: (a, b) \rightarrow \mathbb{R}$ be a function. Suppose f is differentiable at $c \in (a, b)$ and $f'(c) > 0$. Then does there exist an interval around c such that f is increasing on that interval?*

Solution. No. Consider

$$f(x) = \begin{cases} x^2 \sin \frac{1}{x} + \frac{1}{2}x & \text{if } x \neq 0, \\ 0 & \text{if } x = 0. \end{cases}$$

$f'(0) = 0$, and for $x \neq 0$,

$$f'(x) = 2x \sin \frac{1}{x} - \cos \frac{1}{x} + \frac{1}{2}.$$

This attains negative values in any neighbourhood of 0. Thus f is not increasing in any neighbourhood of 0. \blacksquare

Exercise V.2.3. *Let $f: (a, b) \rightarrow \mathbb{R}$ be differentiable. Suppose $f'(x) \geq 0$ for all $x \in (a, b)$, and furthermore that*

- *f' is not identically zero on any interval. Is f strictly increasing on (a, b) ?*

- f' is zero on a discrete set of points. Is f strictly increasing on (a, b) ?

Theorem V.2.4 (Intermediate value property). Suppose $f: (p, q) \rightarrow \mathbb{R}$ is differentiable and $a < b \in (p, q)$. Suppose $f'(a) < \lambda < f'(b)$. Then there exists a $c \in (a, b)$ such that $f'(c) = \lambda$.

Exercise V.2.5. If $g: (a, b) \rightarrow \mathbb{R}$ has a simple discontinuity at $c \in (a, b)$, then g does not satisfy the intermediate value property on some neighbourhood of c .

Proof. We have two cases.

$f(c^-) = f(c^+) = L \neq f(c)$. Choose $\lambda = \frac{1}{2}(L + f(c))$. In some δ neighbourhood of c (excluding c itself), we have $f(x) - L < \frac{1}{2}(f(c) - L)$ so that $f(x) < \lambda$. At c itself, we have $f(c) > \lambda$. Thus λ is never attained.

$f(c^-) \neq f(c^+)$. Choose λ between the two limits, but unequal to $f(c)$. \square

Exercise V.2.6. Show that if a function has a discontinuity of the first kind, then it cannot satisfy the intermediate value property.

Corollary V.2.7. Let $f: (p, q) \rightarrow \mathbb{R}$ be differentiable. Then f' only has discontinuities of the second kind.

Proof of theorem V.2.4. Let $g(x) = f(x) - \lambda x$ for $x \in (p, q) \supseteq [a, b]$. Then $g'(x) = f'(x) - \lambda$ so that $g'(a) < 0 < g'(b)$. This means that g is strictly decreasing from a and strictly increasing to b .

Thus g attains a minimum at some $c \in (a, b)$. Then $g'(c) = 0$ so that $f'(c) = \lambda$. \square

Theorem V.2.8 (Generalised mean value theorem). Let $f, g: [a, b] \rightarrow \mathbb{R}$ be continuous functions that are differentiable on (a, b) . Then there exists a $c \in (a, b)$ such that

$$(f(b) - f(a))g'(c) = (g(b) - g(a))f'(c).$$

Remark. This is also called the Cauchy mean value theorem.

If $g(x) = x$, we recover the mean value theorem. If furthermore $f(a) = f(b)$, we recover Rolle's theorem.

One interpretation is that the ratio of the average rate of change of two functions is achieved by the ratio of their instantaneous rates of change at some point.

Another is that if $x \mapsto (f(x), g(x))$ is a path in \mathbb{R}^2 , then the line joining the endpoints of the path is parallel to the tangent at some point on the path.

Lecture 29.

Wednesday

March 20

Proof. Let

$$h(x) = (f(b) - f(a))g(x) - (g(b) - g(a))f(x).$$

Then

$$\begin{aligned} h(a) &= f(b)g(a) - \cancel{f(a)g(a)} - g(b)f(a) + \cancel{g(a)f(a)} \\ &= f(b)g(a) - g(b)f(a) \\ h(b) &= \cancel{f(b)g(b)} - f(a)g(b) - \cancel{g(b)f(b)} + g(a)f(b) \\ &= f(b)g(a) - g(b)f(a). \end{aligned}$$

Thus $h(a) = h(b)$. By Rolle's theorem, there exists $c \in (a, b)$ such that $h'(c) = 0$. This proves the result. \square

Exercise V.2.9. *Prove that if $f: (a, b) \rightarrow \mathbb{R}$ is differentiable on (a, b) with $f' > 0$ on the entire interval, then f is strictly increasing.*

Similarly if $f' \geq 0$ on the entire interval, then f is weakly increasing.

Proof. Let $x, y \in (a, b)$ with $x < y$. Suppose $f(x) \geq f(y)$. Then by the mean value theorem, there exists $c \in (x, y)$ such that $f'(c) = \frac{f(y) - f(x)}{y - x} \leq 0$.

If $f(x) > f(y)$, then $f'(c) < 0$. This proves both parts of the exercise. \square

Theorem V.2.10 (Taylor's theorem). *Let $n \in \mathbb{N}^*$. Suppose that $f: (a, b) \rightarrow \mathbb{R}$ is n times differentiable on (a, b) . Further assume that $f, f', \dots, f^{(n-1)}$ extend continuously to $[a, b]$. Then there exists a point $c \in (a, b)$ such that*

$$f(b) = f(a) + f'(a)(b-a) + \dots + \frac{f^{(n-1)}(a)}{(n-1)!}(b-a)^{n-1} + \frac{f^{(n)}(c)}{n!}(b-a)^n.$$

Proof. Suppose the result holds in the case when

$$f(a) = f'(a) = \dots = f^{(n-1)}(a) = 0. \quad (\star)$$

Let f be given as per the theorem. Define

$$\begin{aligned} F(x) &= f(x) - \sum_{j=0}^{n-1} \frac{f^{(j)}(a)}{j!} (x-a)^j \\ \implies F^{(k)}(x) &= f^{(k)}(x) - f^{(k)}(a) - \sum_{j=k+1}^{n-1} a_j (x-a)^{j-k} \\ \implies F^{(k)}(a) &= 0 \end{aligned}$$

for every $k \in \{0, 1, \dots, n-1\}$.

Then from the case (\star) , there exists $c \in (a, b)$ such that

$$F(b) = \frac{F^{(n)}(c)}{n!} (b-a)^n.$$

But $F^{(n)} = f^{(n)}$, so this immediately gives

$$f(b) = f(a) + f'(a)(b-a) + \dots + \frac{f^{(n-1)}(a)}{(n-1)!} (b-a)^{n-1} + \frac{f^{(n)}(c)}{n!} (b-a)^n.$$

But how do we prove the case (\star) ?

Suppose f satisfies (\star) . Define

$$g(x) = f(x) - f(b) \frac{(x-a)^n}{(b-a)^n}.$$

This ensures that $g(a) = g(b) = 0$, and since derivatives of f extend continuously to $[a, b]$, so do the derivatives of g . Then $g'(a) = g''(a) = \dots = g^{(n-1)}(a) = 0$. For the n th derivative,

$$g^{(n)}(x) = f^{(n)}(x) - \frac{f(b)n!}{(b-a)^n}.$$

Now apply Rolle's theorem iteratively to $g, g', \dots, g^{(n-1)}$.

(1) From the first application, there exists $c_1 \in (a, b)$ such that $g'(c_1) = 0$.

(2) But $g'(a)$ is also zero, so by a second application there exists $c_2 \in (a, c_1)$ such that $g''(c_2) = 0$.

\vdots

$(n-1)$ Continuing in this way, we find c_{n-1} such that $g^{(n-1)}(c_{n-1}) = 0$.

(n) In the final application, we find $c_n \in (a, c_{n-1})$ such that

$$g^{(n)}(c_n) = f^{(n)}(c_n) - \frac{f(b)n!}{(b-a)^n} = 0.$$

Thus finally, we have that there exists a point $c_n \in (a, b)$ such that $f(b) = \frac{(b-a)^n}{n!} f^{(n)}(c_n)$. This proves the case (\star), and hence the theorem. \square

Theorem V.2.11 (L'Hôpital's rule). *Let $a, b \in \overline{\mathbb{R}}$. Suppose $f, g: (a, b) \rightarrow \mathbb{R}$ are differentiable on (a, b) , and that g and g' are never zero on (a, b) . Suppose also that there exists an $A \in \mathbb{R}$ such that*

$$\lim_{x \downarrow a} \frac{f'(x)}{g'(x)} = A.$$

Then

$$\lim_{x \downarrow a} \frac{f(x)}{g(x)} = A$$

whenever any of the following conditions hold.

- (i) $\lim_{x \downarrow a} f(x) = \lim_{x \downarrow a} g(x) = 0$, or
- (ii) $\lim_{x \downarrow a} g(x) = +\infty$, or
- (iii) $\lim_{x \downarrow a} g(x) = -\infty$.

Case 1. Suppose $\lim_{x \downarrow a} f(x) = \lim_{x \downarrow a} g(x) = 0$. We will only consider the case when $a, A \in \mathbb{R}$.

Let $\varepsilon > 0$. Then there exists $\delta > 0$ such that for every $x \in (a, a + \delta)$,

$$A - \varepsilon < \frac{f'(x)}{g'(x)} < A + \varepsilon.$$

Fix a $y \in (a, a + \delta)$. Let $(z_n)_{n \in \mathbb{N}} \subseteq (a, y)$ be a sequence converging to a such that $g(z_n)$ is never $g(y)$.¹

Then by the generalized mean value theorem, for every $n \in \mathbb{N}$, there exists

¹Why does such a sequence exist? Since g' is never zero on (a, b) , it cannot be constant on any interval. Thus every interval $(a, a + \frac{1}{n}) \cap (a, b)$ contains a point z_n such that $g(z_n) \neq g(y)$.

a $w_n \in (z_n, y)$ such that

$$\frac{f(y) - f(z_n)}{g(y) - g(z_n)} = \frac{f'(w_n)}{g'(w_n)}.$$

But then

$$A - \varepsilon < \frac{f(y) - f(z_n)}{g(y) - g(z_n)} < A + \varepsilon.$$

Taking limits as $n \rightarrow \infty$, we find

$$A - \varepsilon < \frac{f(y)}{g(y)} < A + \varepsilon.$$

Since $\varepsilon > 0$ was arbitrary, we have that

$$\lim_{y \downarrow a} \frac{f(y)}{g(y)} = A.$$

□

Lecture 30.

Friday

March 22

Case 2. Suppose that $\lim_{x \downarrow a} g(x) = +\infty$. Let $\varepsilon > 0$ and again choose δ such that for every $x \in (a, a + \delta)$,

$$\left| \frac{f'(x)}{g'(x)} - A \right| < \varepsilon.$$

Fix a $y \in (a, b)$. Then there exists a $\delta' \in (0, \delta)$ such that for every $z \in (a, a + \delta')$,

$$g(z) > |g(y)| + 1 > g(y), 0.$$

I cannot follow Purvi's proof.

□

V.3 Vector-valued Functions

The definition is identical to the scalar case, the only point being how to interpret the limit in the definition.

Definition V.3.1 (Differentiation). Let $f: (a, b) \rightarrow \mathbb{R}^n$ and $c \in (a, b)$. We say that f is *differentiable at c* with derivative $f'(c)$ if

$$\lim_{h \rightarrow 0} \left\| \frac{f(c+h) - f(c)}{h} - f'(c) \right\| = 0.$$

We say that f is *differentiable* if it is differentiable at each $c \in (a, b)$, and the map f' is called the *derivative* of f .

Remarks.

- If $f(x) = (f_1(x), f_2(x), \dots, f_n(x))$, then f is differentiable at c iff each f_i is differentiable at c , and

$$f'(c) = (f'_1(c), f'_2(c), \dots, f'_n(c)).$$

- If $f, g: (a, b) \rightarrow \mathbb{R}^n$ are differentiable at some c , then

$$\begin{aligned} (f + g)'(c) &= f'(c) + g'(c), \\ \langle f, g \rangle'(c) &= \langle f'(c), g(c) \rangle + \langle f(c), g'(c) \rangle, \end{aligned}$$

Theorem V.3.2 (Mean value inequality). *Suppose $f: [a, b] \rightarrow \mathbb{R}^n$ is continuous on $[a, b]$ and differentiable on (a, b) . Then there exists a $c \in (a, b)$ such that*

$$\|f(b) - f(a)\| \leq (b - a)\|f'(c)\|.$$

Proof. Let $g(x) = \langle f(x), f(b) - f(a) \rangle$. Then g is continuous on $[a, b]$ and differentiable on (a, b) . By the mean value theorem, there exists a $c \in (a, b)$ such that

$$\begin{aligned} g(b) - g(a) &= g'(c)(b - a) \\ \|f(b) - f(a)\|^2 &= \langle f'(c), f(b) - f(a) \rangle (b - a) \\ &\leq \|f'(c)\| \|f(b) - f(a)\| (b - a), \end{aligned}$$

so that

$$\|f(b) - f(a)\| \leq \|f'(c)\| (b - a).$$

(if $f(b) = f(a)$, the inequality is trivially true). □

Chapter VI

Riemann Integration

VI.1 Real-valued Functions

Definition VI.1.1 (Partition). Let $f: [a, b] \rightarrow \mathbb{R}$ be a bounded function. A *partition* of $[a, b]$ is

$$P = \{x_0 \leq x_1 \leq \cdots \leq x_n\}$$

where $x_0 = a$ and $x_n = b$.

We write

$$\begin{aligned}\Delta x_j &:= \Delta_j := x_j - x_{j-1}, \\ M_j &:= \sup_{[x_{j-1}, x_j]} f, \\ m_j &:= \inf_{[x_{j-1}, x_j]} f, \\ \mathcal{U}(P, f) &:= \sum_{j=1}^n M_j \Delta x_j, \\ \mathcal{L}(P, f) &:= \sum_{j=1}^n m_j \Delta x_j.\end{aligned}$$

Lecture 31.

Monday
March 25

Definition VI.1.2 (Riemann integration). We use these to define

$$\overline{\int_a^b} f(x)dx = \inf\{\mathcal{U}(P, f) \mid P \text{ is a partition of } [a, b]\},$$

$$\underline{\int_a^b} f(x)dx = \sup\{\mathcal{L}(P, f) \mid P \text{ is a partition of } [a, b]\}.$$

If $\overline{\int_a^b} f(x)dx = \underline{\int_a^b} f(x)dx = L$, we say that f is *Riemann integrable* on $[a, b]$ and that

$$\int_a^b f(x)dx = L.$$

We denote the family of Riemann integrable functions on $[a, b]$ by $\mathcal{R}([a, b])$.

Lemma VI.1.3. Let P^* be a refinement of P , i.e., P^* partitions $[a, b]$ and $P \subseteq P^*$. Then

$$\mathcal{L}(P, f) \leq \mathcal{L}(P^*, f),$$

$$\mathcal{U}(P^*, f) \leq \mathcal{U}(P, f).$$

Proof. Induct on $|P^* \setminus P|$. Trivial for $|P^* \setminus P| = 0$.

Suppose the result holds for $|P^* \setminus P| = n$. Let P^* be a refinement of P with $|P^* \setminus P| = n + 1$. Let $P^* = P^* \setminus \{y\}$, for some $y \in P^* \setminus P$. Then P^* is a refinement of P^* with just one extra point.

Let

$$P^* = \{x_0 \leq x_1 \leq \cdots \leq x_k \leq y \leq x_{k+1} \leq \cdots \leq x_m\}.$$

Then

$$\begin{aligned} \mathcal{L}(P^*, f) - \mathcal{L}(P^*, f) &= (y - x_k) \inf_{[x_k, y]} f + (x_{k+1} - y) \inf_{[y, x_{k+1}]} f - (x_{k+1} - x_k) \inf_{[x_k, x_{k+1}]} f \\ &\geq (y - x_k) \inf_{[x_k, x_{k+1}]} f + (x_{k+1} - y) \inf_{[x_k, x_{k+1}]} f - (x_{k+1} - x_k) \inf_{[x_k, x_{k+1}]} f \\ &= 0. \end{aligned}$$

Similarly, $\mathcal{U}(P^*, f) - \mathcal{U}(P^*, f) \leq 0$. Thus

$$\mathcal{L}(P, f) \leq \mathcal{L}(P^*, f) \leq \mathcal{L}(P^*, f)$$

$$\mathcal{U}(P, f) \geq \mathcal{U}(P^*, f) \geq \mathcal{U}(P^*, f).$$

Winduction. □

Lemma VI.1.4. *Let P_1 and P_2 be partitions of $[a, b]$. Then*

$$\mathcal{L}(P_1, f) \leq \mathcal{U}(P_2, f).$$

Proof. Let $P^* = P_1 \cup P_2$, which refines both. Then

$$\mathcal{L}(P_1, f) \leq \mathcal{L}(P^*, f) \leq \mathcal{U}(P^*, f) \leq \mathcal{U}(P_2, f). \quad \square$$

Corollary VI.1.5. *$\int_a^b f(x)dx$ and $\overline{\int_a^b f(x)dx}$ are well-defined in \mathbb{R} , and*

$$\int_a^b f(x)dx \leq \overline{\int_a^b f(x)dx}.$$

Theorem VI.1.6. *f is Riemann integrable on $[a, b]$ iff for every $\varepsilon > 0$, there exists a partition P_ε of $[a, b]$ such that*

$$\mathcal{U}(P_\varepsilon, f) - \mathcal{L}(P_\varepsilon, f) < \varepsilon.$$

Proof. For the “if” direction, let $\varepsilon > 0$. Then $\mathcal{U}(P_\varepsilon, f) - \mathcal{L}(P_\varepsilon, f) < \varepsilon$. So $\inf_P \mathcal{U}(P, f) - \sup_P \mathcal{L}(P, f) < \varepsilon$. Since this is true for all $\varepsilon > 0$, we have that they are equal.

For the “only if” direction, let $\varepsilon > 0$. There exists a partition P such that

$$\overline{\int_a^b f(x)dx} \leq \mathcal{U}(P, f) < \overline{\int_a^b f(x)dx} + \frac{\varepsilon}{2}.$$

Similarly, there exists a partition P' such that

$$\int_a^b f(x)dx \geq \mathcal{L}(P', f) > \int_a^b f(x)dx - \frac{\varepsilon}{2}.$$

But $\overline{\int_a^b f(x)dx} = \int_a^b f(x)dx$! So both $\mathcal{U}(P, f)$ and $\mathcal{L}(P', f)$ are within $\varepsilon/2$ of $\int_a^b f(x)dx$.

Let P^* be their common refinement. Then

$$\mathcal{U}(P^*, f) - \mathcal{L}(P^*, f) \leq \mathcal{U}(P, f) - \mathcal{L}(P', f) < \varepsilon. \quad \square$$

Remarks.

- $\mathcal{U}(P_\varepsilon, f) - \mathcal{L}(P_\varepsilon, f) < \varepsilon$ continues to hold for any refinement of P_ε .

- Suppose $\mathcal{U} - \mathcal{L} < \varepsilon$ holds for P_ε , and $s_j, t_j \in [x_{j-1}, x_j] \forall j \in [n]$. Then

$$\sum_{j=1}^n |f(s_j) - f(t_j)| \Delta x_j \leq \mathcal{U} - \mathcal{L} < \varepsilon.$$

- Suppose f is Riemann integrable and $\mathcal{U} - \mathcal{L} < \varepsilon$ holds. Then for any $t_j \in [x_{j-1}, x_j]$,

$$\left| \int_a^b f(x) dx - \sum_{j=1}^n f(t_j) \Delta x_j \right| < \varepsilon.$$

Exercise VI.1.7. Every monotone function on $[a, b]$ is Riemann integrable.

Proof. WLOG suppose that $f: [a, b] \rightarrow \mathbb{R}$ is increasing. First note that f is bounded, specifically by $f(a)$ below and $f(b)$ above. \square

Theorem VI.1.8. Let $f \in \mathcal{R}[a, b]$ with $f[a, b] \subseteq [m, M]$, and let $\phi: [m, M] \rightarrow \mathbb{R}$ be a continuous function. Then

$$\phi \circ f \in \mathcal{R}[a, b].$$

Proof. Let $\phi([m, M]) = [\bar{m}, \bar{M}]$. Let $\varepsilon > 0$. \square

VI.2 Vector-valued Functions

Definition VI.2.1. Let $f: [a, b] \rightarrow \mathbb{R}^n$, $f = (f_1, \dots, f_n)$. Then f is said to be *Riemann integrable* if each f_i is Riemann integrable, and in this case we define

$$\int_a^b f(x) dx = \left(\int_a^b f_1(x) dx, \dots, \int_a^b f_n(x) dx \right).$$

Theorem VI.2.2. Suppose $\vec{f} \in \mathcal{R}[a, b]$. Then so is $\|\vec{f}\|: [a, b] \rightarrow [0, \infty)$, and

$$\left\| \int_a^b \vec{f}(x) dx \right\| \leq \int_a^b \|\vec{f}(x)\| dx.$$

Proof.

$$\|\vec{f}(x)\| = \sqrt{f_1^2(x) + \dots + f_n^2(x)}$$

Lecture 32.

is Riemann integrable since each f_i is, and the square and square root functions are continuous.

Cauchy-Schwarz. For any $f, g: [a, b] \rightarrow \mathbb{R}^n$,

$$\begin{aligned} \langle f(x), g(x) \rangle &\leq \|f(x)\| \|g(x)\| \\ \implies \int_a^b \langle f(x), g(x) \rangle dx &\leq \int_a^b \|f(x)\| \|g(x)\| dx. \end{aligned}$$

The LHS is

$$\sum_i \int_a^b f_i(x) g_i(x) dx.$$

Take $g_j(x) = \int_a^b f_j(t) dt$. Then this becomes

$$\sum_i \left(\int_a^b f_i(x) dx \right)^2 = \left\| \int_a^b f(x) dx \right\|^2.$$

For the RHS, note that g is constant, and

$$\|g(x)\| = \left\| \int_a^b f(t) dt \right\|.$$

So the RHS becomes

$$\left\| \int_a^b f(x) dx \right\| \int_a^b \|f(x)\| dx.$$

Thus

$$\left\| \int_a^b f(x) dx \right\|^2 \leq \left\| \int_a^b f(x) dx \right\| \int_a^b \|f(x)\| dx.$$

If $\left\| \int_a^b f(x) dx \right\| \neq 0$, cancel it out. Otherwise, the inequality holds anyway. \square

VI.3 Rectifiable Paths

Definition VI.3.1 (Path). A *path* or *curve* in \mathbb{R}^n is a continuous function $\gamma: [a, b] \rightarrow \mathbb{R}^n$.

γ is an *arc* if it is injective.

γ is *closed* if $\gamma(a) = \gamma(b)$.

γ is a *simple closed curve* if $\gamma(a) = \gamma(b)$ and the image of γ does not self-intersect.

Definition VI.3.2 (Length and rectifiable paths). Let $\gamma: [a, b] \rightarrow \mathbb{R}^n$ be a path. Let $P = \{a = x_0 \leq x_1 \leq \cdots \leq x_n = b\}$ be a partition of $[a, b]$. Define

$$\Lambda(P, \gamma) = \sum_{i=1}^n \|\gamma(x_i) - \gamma(x_{i-1})\|.$$

Further define

$$\Lambda(\gamma) = \sup\{\Lambda(P, \gamma) \mid P \text{ partitions } [a, b]\}.$$

If $\Lambda(\gamma) < \infty$, then γ is said to be *rectifiable*, and its *length* is defined to be $\Lambda(\gamma)$.

Theorem VI.3.3. Let $\gamma: [a, b] \rightarrow \mathbb{R}^n$ be continuously differentiable. Then γ is rectifiable, and

$$\Lambda(\gamma) = \int_a^b \|\gamma'(t)\| dt.$$

Proof. First note that $\|\gamma'\|$ is continuous, and thus Riemann integrable.

Let $P = \{x_0 \leq \cdots \leq x_n\}$ partition $[a, b]$. By IIFToC,

$$\begin{aligned} \gamma(x_j) - \gamma(x_{j-1}) &= \int_{x_{j-1}}^{x_j} \gamma'(t) dt \\ \implies \|\gamma(x_j) - \gamma(x_{j-1})\| &\leq \int_{x_{j-1}}^{x_j} \|\gamma'(t)\| dt. \end{aligned}$$

by theorem VI.2.2. Summing over all j ,

$$\Lambda(P, \gamma) \leq \int_a^b \|\gamma'(t)\| dt. \quad (\text{VI.1})$$

Thus $\Lambda(\gamma) \leq \int_a^b \|\gamma'(t)\| dt$.

It remains to show that $\Lambda(\gamma) \geq \int_a^b \|\gamma'(t)\| dt$.

γ' is uniformly continuous. Let $\varepsilon > 0$. $\exists \delta > 0$ such that $\forall x, y \in [a, b]$ with $|x - y| < \delta$,

$$\|\gamma'(x) - \gamma'(y)\| < \varepsilon.$$

Let $P_\varepsilon = \{x_0 \leq \cdots \leq x_n\}$ be a partition with each interval of length less than δ . Then for any $t \in [x_{j-1}, x_j]$,

$$\begin{aligned} \|\gamma'(t)\| &\leq \|\gamma'(x_{j-1})\| + \varepsilon \\ \implies \int_{x_{j-1}}^{x_j} \|\gamma'(t)\| dt &\leq \int_{x_{j-1}}^{x_j} \|\gamma'(x_{j-1})\| dt + \varepsilon(x_j - x_{j-1}). \end{aligned}$$

We focus on the first term.

$$\begin{aligned}
\int_{x_{j-1}}^{x_j} \|\gamma'(x_{j-1})\| dt &= \left\| \int_{x_{j-1}}^{x_j} \gamma'(x_{j-1}) dt \right\| \\
&= \left\| \int_{x_{j-1}}^{x_j} \gamma'(x_{j-1}) - \gamma'(t) + \gamma'(t) dt \right\| \\
&\leq \left\| \int_{x_{j-1}}^{x_j} \gamma'(x_{j-1}) - \gamma'(t) dt \right\| + \left\| \int_{x_{j-1}}^{x_j} \gamma'(t) dt \right\| \\
&< \varepsilon(x_j - x_{j-1}) + \|\gamma(x_j) - \gamma(x_{j-1})\|.
\end{aligned}$$

So

$$\int_{x_{j-1}}^{x_j} \|\gamma'(t)\| dt < \|\gamma(x_j) - \gamma(x_{j-1})\| + 2\varepsilon(x_j - x_{j-1}).$$

Summing over all j ,

$$\int_a^b \|\gamma'(t)\| dt \leq \Lambda(P_\varepsilon, \gamma) + 2\varepsilon(b - a). \quad (\text{VI.2})$$

Since ε was arbitrary,

$$\int_a^b \|\gamma'(t)\| dt \leq \Lambda(\gamma).$$

Or is it “taking limits as $\varepsilon \rightarrow 0$ ”?

This should be obvious to me by now, but it's not. So lemme do some ε -stuff.

$\Lambda(\gamma)$ is the supremum of $\Lambda(P, \gamma)$ over all partitions P . So for any $\varepsilon > 0$, there exists a partition P such that

$$\Lambda(P, \gamma) > \Lambda(\gamma) - \varepsilon. \quad (\text{VI.3})$$

In fact, it is the unique upper bound that satisfies this.

We have already shown that the speed integral is an upper bound. From equation (VI.2), we have shown the property (VI.3). Thus $\int_a^b \|\gamma'(t)\| dt$ is the desired supremum.

More directly, there are partitions that make $\Lambda(\cdot, \gamma)$ arbitrarily close to the speed integral. So nothing less than the speed integral can be an upper bound. Thus $\Lambda(\gamma) \leq \int_a^b \|\gamma'(t)\| dt$.

Combining this with (VI.1), we have

$$\Lambda(\gamma) = \int_a^b \|\gamma'(t)\| dt. \quad \square$$

Theorem VI.3.4. Let $f_n \in \mathcal{D}((a, b))$ and $f'_n \rightarrow g$. Suppose $f_n(x_0) \rightarrow f(x_0)$ for some $x_0 \in (a, b)$.

Proof. WLOG assume that $x > x_0$. Apply MVT to $f_n - f_m$ on $[x_0, x]$.

There exists a $\theta_{mn} \in (x_0, x)$ such that

$$(f_n - f_m)(x) - (f_n - f_m)(x_0) = (f'_n - f'_m)(\theta_{mn})(x - x_0) \quad (\text{VI.4})$$

Let $\varepsilon > 0$. Then for m, n beyond some N ,

$$\begin{aligned} |f_n(x_0) - f_m(x_0)| &< \frac{\varepsilon}{2} \\ |f'_n(t) - f'_m(t)| &< \frac{\varepsilon}{2(b-a)} \quad \forall t \in [x_0, x] \end{aligned}$$

Applying this to equation (VI.4),

$$\begin{aligned} |f_n(x) - f_m(x)| &\leq |f_n(x_0) - f_m(x_0)| + |f'_n(\theta_{mn}) - f'_m(\theta_{mn})||x - x_0| \\ &< \frac{\varepsilon}{2} + \frac{\varepsilon(x - x_0)}{2(b-a)} \\ &< \varepsilon. \end{aligned}$$

Thus by the Cauchy criterion, $f_n \rightarrow f$ on (a, b) .

Fix a $p \in (a, b)$. Let $\phi_n: (a, b) \setminus \{p\} \rightarrow \mathbb{R}$ be the difference quotient

$$\phi_n(x) = \lim_{x \rightarrow p} \frac{f_n(x) - f_n(p)}{x - p}$$

and similarly $\phi(x) = \lim_{x \rightarrow p} \frac{f(x) - f(p)}{x - p}$.

We show that ϕ_n is uniformly Cauchy and $\phi_n \rightarrow \phi$ on $(a, b) \setminus \{p\}$.

$$\begin{aligned} \phi_n(x) - \phi_m(x) &= \frac{(f_n - f_m)(x) - (f_n - f_m)(p)}{x - p} \\ &= (f'_n - f'_m)(\theta) \end{aligned}$$

for some θ between x and p (by MVT). Thus $\phi_n \rightarrow \phi$ for some h .

But now fix an x .

$$\lim_{n \rightarrow \infty} \frac{f_n(x) - f_n(p)}{x - p} = \frac{f(x) - f(p)}{x - p} = \phi(x),$$

so $\phi_n \xrightarrow{p.w.} \phi$.

But uniform convergence implies pointwise convergence, and so $\phi_n \xrightarrow{p.w.} h$ which means that $h = \phi$.

By ??,

$$\begin{aligned} \lim_{n \rightarrow \infty} \lim_{x \rightarrow p} \phi_n(x) &= \lim_{x \rightarrow p} \phi(x) \\ \implies \lim_{n \rightarrow \infty} f'_n(p) &= f'(p) \end{aligned}$$

Thus $f'_n(p) \rightarrow g(p)$. By IFTOC, □

VI.3.1 The Function

Start with $\phi(x) = |x|$ on $[-1, 1]$, and extend it by periodicity to the entire number line.

Define

$$f_k := \left(\frac{3}{4}\right)^k \phi(4^k \cdot)$$

and

$$f := \sum_{k=0}^{\infty} f_k$$

By the Weierstrass M -test, f is continuous, since

$$|f_k| \leq \left(\frac{3}{4}\right)^k \text{ and } \sum \left(\frac{3}{4}\right)^k < \infty.$$

Fix an $x \in \mathbb{R}$. Also fix an $m \in \mathbb{N}$. There is at most one integer in the $\frac{1}{2}$ -ball around any point, so WLOG assume that $(4^m x, 4^m x + \frac{1}{2})$ contains no integer.

Let $\delta_m = 4^{-m} \frac{1}{2}$.

$$\frac{f(x + \delta_m) - f(x)}{\delta_m} = \sum_{k=0}^{\infty} \left(\frac{3}{4}\right)^k \frac{\phi(4^k(x + \delta_m)) - \phi(4^k x)}{\delta_m}$$

But for $k > m$, $4^k \delta_m = 4^{k-m} \frac{1}{2}$ is an even integer, so by the periodicity of ϕ , the summand vanishes.

For $k = m$, the summand becomes

$$\left(\frac{3}{4}\right)^m \frac{\phi(4^m x + \frac{1}{2}) - \phi(4^m x)}{\delta_m}$$

whose absolute value is exactly 4^m .
